Abstract

This paper studies the problem of nonparametric testing for the effect of a random functional covariate on a real-valued error term. The covariate takes values in $L^2[0, 1]$, the Hilbert space of the square-integrable real-valued functions on the unit interval. The error term could be directly observed as a response or *estimated* from a functional parametric model, like for instance the functional linear regression. Our test is based on the remark that checking the no-effect of the functional covariate is equivalent to checking the nullity of the conditional expectation of the error term given a sufficiently rich set of projections of the covariate. Such projections could be on elements of norm 1 from finite-dimension subspaces of $L^2[0, 1]$. Next, the idea is to search a finite-dimension element of norm 1 that is, in some sense, the least favorable for the null hypothesis. Finally, it remains to perform a nonparametric check of the nullity of the conditional expectation of the error term given the scalar product between the covariate and the selected least favorable direction. For such finite-dimension search and nonparametric check we use a kernel-based approach. As a result, our test statistic is a quadratic form based on univariate kernel smoothing and the asymptotic critical values are given by the standard normal law. The test is able to detect nonparametric alternatives, including the polynomial ones. The error term could present heteroscedasticity of unknown form. We do not require the law of the covariate X to be known. The test could be implemented quite easily and performs well in simulations and real data applications. We illustrate the performance of our test for checking the functional linear regression model.

Keywords: functional data regression, kernel smoothing, nonparametric testing

1 Introduction

Consider a sample of independent copies $(U_1, X_1), \dots, (U_n, X_n)$ of (U, X) where U is a real-valued random variable and X is a square-integrable random function defined on the unit interval. The problem we investigate herein is the test of the hypothesis

$$H_0 : \mathbb{E}(U|X) = 0 \quad \text{almost surely (a.s.)} \quad (1.1)$$

against the nonparametric alternative $\mathbb{P}[\mathbb{E}(U|X) = 0] < 1$. We consider two cases: (a) U is directly observed; and (b) U is not observed and is estimated as a residual of a parametric model for functional covariates and scalar responses.

There has been substantial recent work on the theoretical study of the functional data analysis. The monographs of Ramsay and Silverman (2002, 2005) and Ferraty (2011) provide a comprehensive landscape of the importance of the statistical methods for functional data. Estimation and prediction with functional covariates received substantial attention in the literature: for example by Ferraty and Vieu (2006), Cai and Hall (2006), Hall and Horowitz (2007), Crambes, Kneip and Sarda (2008), Yao and Müller (2010) and the references therein.

The goodness-of-fit problem we address seems to be much less explored. There is a large literature on model checks like (1.1) against nonparametric alternatives when X takes values in a finite-dimension space, see for instance Härdle and Mammen (1993), Stute (1997), Horowitz and Spokoiny (2001), Guerre and Lavergne (2005). In the case of functional covariate X , much little work was accomplished for testing against general types of alternatives. To our best knowledge, the only contribution considering the problem of testing H_0 against nonparametric alternatives in the cases (a) and (b) is the recent paper of Delsol, Ferraty and Vieu (2011) who extend the idea of Härdle and Mammen (1993) to the functional covariate case. However, their results are derived under some strong assumptions, like for instance the assumptions on the rates of convergence of the so-called small ball probabilities and the law of the covariate X that are supposed to be known. It is not clear how the test of Delsol, Ferraty and Vieu (2011) could be easily applied in practice, for instance for testing the goodness-of-fit of the functional linear model. Some more substantial work was done for testing for no effect in a functional linear model, see Cardot, Ferraty, Mas and Sarda (2003), Cardot, Goia and Sarda (2007), or for testing the functional linear model against quadratic alternatives, see Horváth and Reeder (2011). By construction, such procedures are not able to detect general departures from the null hypothesis.

The test we introduce herein is based on a dimension reduction idea used by Lavergne and Patilea (2008) in a finite dimension setup. Our test is able to detect *nonparametric* alternatives, including the polynomial ones. The variable U could be heteroscedastic and we do not require the conditional variance of U given X to be known. We do not require the law of the covariate X to be given or to be of a certain type, like for instance Gaussian. The test could be implemented quite easily and performs well in simulations and real data applications.

The paper is organized as follows. In section 2 we introduce the main notation and we derive a fundamental lemma for our approach. This lemma shows that checking condition (1.1) is equivalent to checking the nullity of the conditional expectation of U given a sufficiently rich set of projections of X on elements of norm 1 from finite-dimension subspaces of $L^2[0, 1]$. Next, the idea is to search in finite-dimension subspaces of $L^2[0, 1]$ a least favorable element of norm 1 and to check the nullity of the conditional expectation of U given the scalar product between X and the selected least favorable direction. In section 3 we introduce the test statistic for testing of no-effect of X on U when U is observed. Our statistic is a quadratic form, based on *univariate* kernel smoothing, that behaves like a standard normal random variable under H_0 . We prove that, under mild integrability or boundedness assumptions, the induced test is consistent against *any* type of fixed alternatives and against sequences of directional alternatives approaching the null hypothesis at a suitable rate. The allowed rates are almost the same as those obtained in parametric model checks based on kernel smoothing with *univariate* covariate, see for instance Guerre and Lavergne (2005) or Lavergne and Patilea (2008). In section 4 we apply our projection-based approach for nonparametric checks of the functional regression models. We will focus on the linear functional model, although, at the expense of longer arguments, the methodology we propose also adapts to other models, like for instance the generalized functional linear models introduced by Müller and Stadtmüller (2005). In the functional regression case the variable U is the unobserved error term of the regression model and hence the test statistic is based on the estimated residuals. We still obtain standard normal critical values and consistency against nonparametric alternatives, fixed or approaching the null hypothesis. However, more restrictive conditions on the bandwidths are required due to the estimation of the slope of the functional linear model. This induces restrictions on the rate the directional alternatives may approach the null hypothesis. More difficult the estimation of the slope parameter is, slower the rate the directional alternative approach the null hypothesis should be. For estimating the slope parameter in the functional linear regression model we will focus on the standard approach based on functional principal component analysis. In section 5 an empirical study is reported. First, a wild bootstrap procedure is proposed as a means to approximate the critical values of the test statistic. Then, the results of a simulation study are briefly explained. The conclusion is that the test works well in practice. Under the null, the level is quite well respected and the power is more than acceptable even in the comparison with parametric tests. The proposed test is consistent under general alternatives. Some advices and comments are provided about the choice of the parameters involved in the new test. The test is applied to test the goodness-of-fit of the functional linear model and the functional quadratic model for the Tecator data set. Both models are rejected which indicates that more flexible models should be considered, like for instance the semiparametric index models introduced by Chen, Hall and Müller (2011). The proofs of our theoretical results are relegated to the appendix.

2 Dimension reduction in nonparametric testing

Let us introduce some notation. For any $p \geq 1$, let $\mathcal{S}^p = \{\gamma \in \mathbb{R}^p : \|\gamma\| = 1\}$ denote the unit hypersphere in $\mathbb{R}^p$. Let $L^2[0, 1]$ be the space of the square-integrable real-valued functions defined on the unit interval $\langle \cdot, \cdot \rangle$ denote the inner product in $L^2[0, 1]$, that is for any $X_1, X_2 \in L^2[0, 1]$

$$\langle X_1, X_2 \rangle = \int_0^1 X_1(t)X_2(t)dt.$$

Let $\|\cdot\|_{L^2}$ be the associated norm. Hereafter $\mathcal{R} = \{\rho_1, \rho_2, \dots\}$ will be an arbitrarily fixed orthonormal basis of the function space $L^2[0, 1]$, that is $\langle \rho_i, \rho_j \rangle = \delta_{ij}$. Then the predictor process X can be expanded into

$$X(t) = \sum_{j=1}^{\infty} x_j \rho_j(t), \quad (2.2)$$

where the random coefficients x_j are given by $x_j = \langle X, \rho_j \rangle$. For a fixed positive integer p , $X^{(p)} \in L^2[0, 1]$ will be the projection of X on the subspace generated by the first p elements of the basis $\mathcal{R}$, that is

$$X^{(p)}(t) = \sum_{j=1}^p x_j \rho_j(t).$$

Let us notice that $\|X^{(p)}\|_{L^2}$ coincides with the Euclidean norm of the vector $(x_1, \dots, x_p)$ in $\mathbb{R}^p$. By abuse we also identify $X^{(p)}$ with the p -dimension random vector $(x_1, \dots, x_p)$. On the other hand, for any integer $p > 1$ and non random vector $\gamma = (\gamma_1, \dots, \gamma_p) \in \mathbb{R}^p$, we consider by abuse γ an element in $L^2[0, 1]$ with $(\gamma_1, \dots, \gamma_p, 0, 0, \dots)$ the coefficients of its expansion and hence $\langle X, \gamma \rangle = \langle X^{(p)}, \gamma \rangle = \sum_{i=1}^p x_i \gamma_i$. In the following we will also use $\beta = \sum_{j=1}^{\infty} b_j \rho_j(t)$ to denote a non random element of $L^2[0, 1]$.

Our approach relies on the following lemma, an extension of Lemma 2.1 of Lavergne and Patilea (2008) and Theorem 1 in Bierens (1990) to Hilbert space-valued conditioning random variables. The result shows that for checking nullity of a conditional expectation, it is equivalent to consider expectations conditional on X and expectations conditional on $L^2[0, 1]$ projections of X on a sufficiently rich set of directions.

Lemma 2.1 *Let $X \in L^2[0, 1]$ and $Z \in \mathbb{R}$ be random variables. Assume that $\mathbb{E}|Z| < \infty$ and $\mathbb{E}(Z) = 0$.*

(A) The following statements are equivalent:

1. $\mathbb{E}(Z | X) = 0$ a.s.
2. $\mathbb{E}(Z | \langle X, \beta \rangle) = 0$ a.s. $\forall \beta \in L^2[0, 1]$ with $\|\beta\|_{L^2} = 1$.
3. for any integer $p \geq 1$, $\mathbb{E}(Z | \langle X, \gamma \rangle) = 0$ a.s. $\forall \gamma \in \mathcal{S}^p$.

4. for any integer $p \geq 1$, $\mathbb{E}(Z \mid X^{(p)}) = 0$ a.s.

(B) Suppose in addition that for any positive real number s ,

$$\mathbb{E}(|Z| \exp\{s\|X\|\}) < \infty. \quad (2.3)$$

If $\mathbb{P}[\mathbb{E}(Z \mid X) = 0] < 1$, then there exists a positive integer $p_0 \geq 1$ such that for any integer $p > p_0$, the set

$$\{\gamma \in \mathcal{S}^p : \mathbb{E}(Z \mid \langle X, \gamma \rangle) = 0 \text{ a.s.}\}$$

has Lebesgue measure zero on the unit hypersphere $\mathcal{S}^p$ and is not dense.

Point (A) is a cornerstone for proving the behavior of our test under the null and the alternative hypothesis. Point (B) shows that in applications it will not be difficult to find directions γ able to reveal the failure of the null hypothesis (1.1). Under the additional assumption (2.3) such directions represent almost all the points on the unit hyperspheres $\mathcal{S}^p$, provided p is sufficiently large. The assumption (2.3) is not restrictive for testing purposes. Indeed, if X does not satisfy condition (2.3), it suffices to transform X into some variable $W \in L^2[0, 1]$ such that the σ -field generated by W is the same as the one generated by X and the variable W satisfies condition (2.3).^{*} Clearly, when U is the error term in some functional regression model for which one wants to check the goodness-of-fit, one should use a transformation of X only *after* estimating the errors in the model.

The following new formulations of H_0 are direct consequences of Lemma 2.1-(A).

Corollary 2.2 *Consider a real-valued random variable U such that $\mathbb{E}|U| < \infty$. Let $\omega(\beta, t)$, $\beta \in L^2[0, 1]$ and $t \in \mathbb{R}$, be a real-valued function such that $\omega(\beta, \langle X, \beta \rangle) > 0$ for all $\|\beta\|_{L^2} = 1$. For any $p \geq 1$, let $w_p(\gamma, t)$, $\gamma \in \mathbb{R}^p$ and $t \in \mathbb{R}$, be a real-valued function such that $w_p(\gamma, \langle X, \gamma \rangle) > 0$ for all $\|\gamma\| = 1$. The following statements are equivalent:*

1. The null hypothesis (1.1) holds true.

2.

$$\max_{\beta \in L^2[0,1], \|\beta\|_{L^2}=1} \mathbb{E}[U \mathbb{E}(U \mid \langle X, \beta \rangle) \omega(\beta, \langle X, \beta \rangle)] = 0. \quad (2.4)$$

3. for any $p \geq 1$ and any set $B_p \subset \mathcal{S}^p$ with strictly positive Lebesgue measure on the unit hypersphere $\mathcal{S}^p$,

$$\max_{\gamma \in B_p} \mathbb{E}[U \mathbb{E}(U \mid \langle X, \gamma \rangle) w_p(\gamma, \langle X, \gamma \rangle)] = 0. \quad (2.5)$$

^{*}For instance, given $X = \sum_{j \geq 1} x_j \rho_j$, one may build $w_j = a_j \arctan(x_j)$, where a_j are non random such that $\sum_{j \geq 1} a_j^2 < \infty$ and may use the bounded random function $W = \sum_{j \geq 1} w_j \rho_j \in L^2[0, 1]$ (bounded means $\|W\|$ is a bounded random variable) instead of X in the conditioning.

3 Testing the effect of a functional covariate

We introduce a general approach for nonparametric testing of the effect of a functional covariate X on a real-valued random variable U . For simplicity, here we assume that $\mathbb{E}(U) = 0$, the nonzero mean case is contained in the setup considered in section 4 below. Our approach is based on Corollary 2.2-(3) and *univariate* kernel smoothing. In this way we avoid the problem of smoothing in infinite-dimension, in particular we avoid using the small ball function required in the kernel regression with functional covariates, see Ferraty and Vieu (2006), Delsol, Ferraty and Vieu (2011).

To avoid handling denominators close to zero, we set the weight function $\omega(\gamma, \cdot)$ in Corollary 2.2 equal to the density of $\langle X, \gamma \rangle$, denoted by $f_\gamma(\cdot)$, which is assumed to exist for any γ . For any $\gamma \in \mathbb{R}^p$, let

$$Q(\gamma) = \mathbb{E}\{U \mathbb{E}[U \mid \langle X, \gamma \rangle] f_\gamma(\langle X, \gamma \rangle)\} = \mathbb{E}\{\mathbb{E}^2[U \mid \langle X, \gamma \rangle] f_\gamma(\langle X, \gamma \rangle)\}.$$

For any $p \geq 1$, let $B_p \subset \mathcal{S}^p$ be a set with strictly positive Lebesgue measure in $\mathcal{S}^p$. By Corollary 2.2, the null hypothesis (1.1) holds true if and only if

$$\forall p \geq 1, \quad \max_{\gamma \in B_p} Q(\gamma) = 0. \quad (3.1)$$

3.1 The test statistic

In view of equation (3.1), our goal is to estimate $Q(\gamma)$. With at hand a sample of (U, X) , define

$$Q_n(\gamma) = \frac{1}{n(n-1)} \sum_{1 \leq i \neq j \leq n} U_i U_j \frac{1}{h} K_h(\langle X_i - X_j, \gamma \rangle), \quad \gamma \in \mathcal{S}^p,$$

where $K_h(\cdot) = K(\cdot/h)$, where $K(\cdot)$ is a kernel and h a bandwidth. In the case of finite dimension covariates, the function $\gamma \mapsto Q_n(\gamma)$ is the statistic considered by Lavergne and Patilea (2008), see also Bierens (1990). For fixed p and $\gamma \in \mathcal{S}^p$, it is well-known that $Q_n(\gamma)$ has asymptotic centered normal distribution with rate $nh^{1/2}$ under H_0 ; see for instance Guerre and Lavergne (2005). We will show that the asymptotic normal distribution is preserved even when p grows at a suitable rate with the sample size. On the other hand, Lemma 2.1-(B) indicates that if p is large enough, the maximum of $Q(\gamma)$ over γ stays away from zero when H_0 fails.

For a fixed p the statistic $Q_n(\gamma)$ is expected to be close to $Q(\gamma)$ uniformly in γ . Then a natural idea would be to build a test statistic using the maximum of $Q_n(\gamma)$ with respect to γ . However, there is an additional difficulty one faces in the functional data framework since then one has to let p to grow to infinity with the sample size, and hence the closeness between $Q_n(\gamma)$ and $Q(\gamma)$ requires a more careful investigation. On the other hand, like in the finite dimension covariate case, under H_0 one expects $Q_n(\gamma)$ to converges to zero for any p and γ and thus the objective function of the maximization problem to be flat.

We will choose a direction γ as the least favorable direction for the null hypothesis H_0 obtained from a penalized criterion based on a standardized version of $Q_n(\gamma)$. Lavergne

and Patilea (2008) and Bierens (1990) considered this idea using $Q_n(\gamma)$. Here we use a standardized version of $Q_n(\gamma)$. More precisely, fix some $\beta_0 \in L^2[0, 1]$ that could be interpreted as an initial *guess* of an unfavorable direction for H_0 . Let b_{0j} , $j \geq 1$, be the coefficients in the expansion of β_0 in the basis $\mathcal{R}$. For any given $p \geq 1$ such that $\sum_{j=1}^p b_{0j}^2 > 0$, let

$$\gamma_0^{(p)} = (b_{01}, \dots, b_{0p}) / \sqrt{\sum_{j=1}^p b_{0j}^2} .$$

Let $\widehat{v}_n^2(\cdot)$ be an estimate of the variance of $nh^{1/2}Q_n(\cdot)$. Given $B_p \subset \mathcal{S}^p$ with strictly positive Lebesgue measure in $\mathcal{S}^p$ that contains $\gamma_0^{(p)}$, the least favorable direction γ for H_0 is defined as

$$\widehat{\gamma}_n = \arg \max_{\gamma \in B_p} \left[nh^{1/2}Q_n(\gamma)/\widehat{v}_n(\gamma) - \alpha_n \mathbb{I}_{\{\gamma \neq \gamma_0^{(p)}\}} \right] , \quad (3.2)$$

where $\mathbb{I}_A$ is the indicator function of a set A , and α_n , $n \geq 1$ is a sequence of positive real numbers increasing to infinity at an appropriate rate that depends on the sample size and the rates of h and p and that will be made explicit below. Let us notice that the maximization used to define $\widehat{\gamma}_n \in \mathcal{S}^p$ is a finite dimension optimization problem. The choice of β_0 , and thus of $\gamma_0^{(p)}$, is theoretically irrelevant, it does not affect the asymptotic critical values and the consistency results. However, in practice the choice of β_0 could be related to a priori information of the practitioner on a class of alternatives, like for instance the class of functions depending only on $\langle X, \beta_0 \rangle$. The empirical investigation we report in section 5 suggests that working with a standardized version of $Q_n(\gamma)$ simplifies the choice of α_n in applications.

We will prove that with suitable rates of increase for α_n and p and decrease for h , the probability of the event $\{\widehat{\gamma}_n = \gamma_0^{(p)}\}$ tends to 1 under H_0 . Hence $Q_n(\widehat{\gamma}_n)/\widehat{v}_n(\widehat{\gamma}_n)$ behaves asymptotically like $Q_n(\gamma_0^{(p)})/\widehat{v}_n(\gamma_0^{(p)})$, even when p grows with the sample size. Therefore the test statistic we consider is

$$T_n = nh^{1/2} \frac{Q_n(\widehat{\gamma}_n)}{\widehat{v}_n(\widehat{\gamma}_n)} . \quad (3.3)$$

We will show that an asymptotic α -level test is given by $\mathbb{I}(T_n \geq z_{1-\alpha})$, where $z_{1-\alpha}$ is the $(1 - \alpha)$ -th quantile of the standard normal distribution.

3.2 Estimating the variance

To find the direction $\widehat{\gamma}_n$ and to build the test statistics (3.3), we need to estimate in some way the variance of $nh^{1/2}Q_n(\gamma)$. The approach that is expected not to inflate the variance estimate under the alternatives and thus to guarantee better power small finite samples would involve the estimations of the conditional variance of $nh^{1/2}Q_n(\gamma)$ given X_i 's which writes

$$\tau_n^2(\gamma) = \frac{2}{n(n-1)h} \sum_{j \neq i} \sigma_p^2(X_i^{(p)}) \sigma_p^2(X_j^{(p)}) K_h^2(\langle X_i - X_j, \gamma \rangle) , \quad (3.4)$$

where $\sigma_p^2(X^{(p)}) = \text{Var}[U \mid X^{(p)}]$. An estimator can be easily obtained by replacing $\sigma_p^2(\cdot)$ with an estimate in the last expression. In theory, a good solution would be to use a nonparametric estimate of the p -variate function $\sigma_p^2(\cdot)$, but this is practically infeasible given that it is expected to let p to grow with the sample size. A simple and convenient solution with high-dimension covariates is then

$$\hat{\tau}_n^2(\gamma) = \frac{2}{n(n-1)h} \sum_{j \neq i} U_i^2 U_j^2 K_h^2(\langle X_i - X_j, \gamma \rangle). \quad (3.5)$$

Since, under the null hypothesis $\hat{\gamma}_n = \gamma_0^{(p)}$ with probability tending to 1, a first variance estimator we propose is

$$\hat{v}_n^2(\hat{\gamma}_n) = \hat{v}_n^2(\hat{\gamma}_n, \gamma_0^{(p)}) = \min \left(\hat{\tau}_n^2(\hat{\gamma}_n), \hat{\tau}_n^2(\gamma_0^{(p)}) \right). \quad (3.6)$$

On the other hand, let us notice that $\tau_n^2(\gamma_0^{(p)}) - \mathbb{E}[\tau_n^2(\gamma_0^{(p)})]$ is expected to converge to zero. Moreover, under the null hypothesis

$$\begin{aligned} \mathbb{E}[\tau_n^2(\gamma_0^{(p)})] &= \mathbb{E}[\mathbb{E}[\tau_n^2(\gamma_0^{(p)}) \mid \langle X_1, \gamma_0^{(p)} \rangle, \dots, \langle X_n, \gamma_0^{(p)} \rangle]] \\ &= \mathbb{E} \left\{ \frac{2}{n(n-1)h} \sum_{j \neq i} \text{Var}[U_i \mid \langle X_i, \gamma_0^{(p)} \rangle] \text{Var}[U_j \mid \langle X_j, \gamma_0^{(p)} \rangle] K_h^2(\langle X_i - X_j, \gamma_0^{(p)} \rangle) \right\}, \end{aligned}$$

and $0 < \underline{\sigma}^2 \leq \text{Var}[U \mid \langle X, \gamma_0^{(p)} \rangle] \leq \overline{\sigma}^2 < \infty$. Next, notice that the conditional variance of U given $\langle X, \beta_0 \rangle$ is the same under H_0 and under any alternative that depends only on $\langle X, \beta_0 \rangle$. Finally, notice that in any case $\mathbb{E}(U^2) \geq \mathbb{E}[\text{Var}(U \mid \langle X, \beta_0 \rangle)]$. All these facts suggest that a compromise for estimating the variance of $nh^{1/2}Q_n(\beta_0^{(p)})$ would be

$$\hat{v}_n^2 = \hat{v}_n^2(\gamma_0^{(p)}) = \frac{2}{n(n-1)h} \sum_{j \neq i} \hat{\sigma}_{\gamma_0^{(p)}}^2(\langle X_j, \gamma_0^{(p)} \rangle) \hat{\sigma}_{\gamma_0^{(p)}}^2(\langle X_i, \gamma_0^{(p)} \rangle) K_h^2(\langle X_i - X_j, \gamma_0^{(p)} \rangle), \quad (3.7)$$

where $\hat{\sigma}_{\gamma_0^{(p)}}^2(\cdot)$ is some nonparametric estimate of the univariate function $\sigma_{\gamma_0^{(p)}}^2(t) = \text{Var}(U \mid \langle X, \gamma_0^{(p)} \rangle = t)$ satisfying the condition

$$\sup_{1 \leq i \leq n} \left| \frac{\hat{\sigma}_{\gamma_0^{(p)}}^2(\langle X_i, \gamma_0^{(p)} \rangle)}{\sigma_{\gamma_0^{(p)}}^2(\langle X_i, \gamma_0^{(p)} \rangle)} - 1 \right| = o_{\mathbb{P}}(1), \quad (3.8)$$

Different nonparametric estimators can be used, for instance a kernel estimator like in Lavergne and Patilea (2008). We will prove below that both variance estimators (3.6) and (3.7) guarantee the standard normal asymptotic critical values and consistency of our test. In simulations, better power under the alternative was obtained when using the variance estimator (3.7). The drawback of this estimator is the computational cost and the choice of an additional bandwidth for the estimate $\hat{\sigma}_{\gamma_0^{(p)}}^2(\cdot)$. However, common choices of this bandwidth work well in practice.

3.3 Behavior under the null hypothesis

Let us introduce a first set of assumptions. Below $0_p \in \mathbb{R}^p$ denotes the null vector of dimension p . Moreover, $\mathcal{F}[\cdot]$ denotes the Fourier transform, cf. Rudin (1987).

Assumption D

- (a) *The random vectors $(U_1, X_1), \dots, (U_n, X_n)$ are independent draws from the random vector $(U, X) \in \mathbb{R} \times L^2[0, 1]$ that satisfies $\mathbb{E}|U|^m < \infty$ for some $m > 11$.*
- (b) *$\exists \underline{\sigma}^2$ and $\bar{\sigma}^2$ such that $0 < \underline{\sigma}^2 \leq \text{Var}(U | X) \leq \bar{\sigma}^2 < \infty$ almost surely.*
- (c) *The sets $B_p \subset \mathcal{S}^p$, $p \geq 1$ appearing in (3.2) are such that:*
 - (i) *there exist constants $C_1, \delta > 0$ (independent of n and p) such that $\forall p \geq 1$ and $\forall \gamma \in B_p$, the variable $\langle X, \gamma \rangle$ admits a density $f_\gamma(\cdot)$ and*

$$C_1^{-1} \leq \int_{\mathbb{R}} \{f_\gamma^2 \mathbb{I}(f \leq 1) + f_\gamma^{2+\delta} \mathbb{I}(f > 1)\} \leq C_1;$$

- (ii) *there exists $C_2, \epsilon > 0$ such that $\int_{|x| \leq \epsilon} |\mathcal{F}[f_\gamma]|^2(x) dx \geq C_2$, $\forall p \geq 1$, $\forall \gamma \in B_p$;*
- (iii) *the initial ‘guess’ β_0 satisfies the condition: $\exists C_3$ such that $f_{\gamma_0^{(p)}} \leq C_3$, $\forall p \geq 1$.*
- (iv) *$B_p \times 0_{p'-p} \subset B_{p'}$, $\forall 1 \leq p < p'$.*

Assumption K

- (a) *The kernel K is a continuous density of bounded variation with strictly positive Fourier transform on the real line.*
- (b) *$h \rightarrow 0$ and $(nh^2)^\alpha / \ln n \rightarrow \infty$ for some $\alpha \in (0, 1)$.*
- (c) *$p \geq 1$ increases to infinity with n and there exists a constant $\lambda > 0$ such that $p \ln^{-\lambda} n$ is bounded.*

Let us comment on these assumptions. The bounded variation of K , in particular this means K is bounded, is a very mild condition that allows to easily bound covering numbers of families of functions indexed by γ . Continuity and bounded variation guarantee that K can be recovered by inverse Fourier transform. The role of technical assumption of positive Fourier, that is satisfied by triangular, normal, logistic, Student, or Laplace densities, will be explained below. In Assumption K-(c), it is also possible to let p to grow with the sample size at a polynomial rate, instead of the logarithmic rate. However, we will see below that, in theory, this could induce a loss of power for our test. There is a trade off between the moment conditions one imposes for U and the range of rates allowed for the bandwidth and the growth rate for p : higher moments will be needed for wider ranges and faster rates for p . For bandwidths and p satisfying Assumption K-(b,c) it suffices

to take $m > 11$ in Assumption D-(a); see the proof of Lemma 3.1. Let us notice that Assumption D-(b) implies that $\forall p \geq 1$, $0 < \underline{\sigma}^2 \leq \mathbb{E}(U^2 \mid X^{(p)}) \leq \bar{\sigma}^2 < \infty$ almost surely. Finally, let us comment on Assumption D-(c). On one hand, a key issue in the proof of Lemma 3.1 below and some of the subsequent proofs will be to control the rate of $\mathbb{E}[h^{-1}K_h(\langle X_1 - X_2, \gamma \rangle)]$ uniformly in $\gamma \in B_p$ as p grows and h decreases with the sample size. To reduce technicalities, we choose the convenient solution that consists in trying to bound this quantity by a constant. Using the Fourier transform and Plancherel theorem, this is guaranteed by a condition like $\int_{\mathbb{R}} f_{\gamma}^2 \leq C_1, \forall \gamma \in B_p$. In the proofs for the functional linear model we have to strengthen this condition and add $\int_{\mathbb{R}} f_{\gamma}^{2+\delta} \mathbb{I}(f > 1) \leq C_1, \forall \gamma \in B_p$, for some arbitrary small $\delta > 0$. Such sufficient conditions could be easily achieved for instance if the coefficients x_j of the expansion of X are independent. Then it suffices to fix some $k \geq 1$ such that the density of x_k is bounded and some small c independent of p and to take $B_p = \{(\gamma_1, \dots, \gamma_k, \dots, \gamma_p) \in \mathcal{S}^p : |\gamma_k| \geq c\}$. This simple idea could be useful in many other cases than the one of independent coefficients x_j . On the other hand, we have to keep the variance estimate in the denominator of the test statistic (3.3) away from zero. For this we have to ensure that $\mathbb{E}[h^{-1}K_h^2(\langle X_1 - X_2, \gamma \rangle)]$ is bounded away from zero uniformly in $\gamma \in B_p$ as p grows and h decreases with the sample size. One easy way to ensure this is to use again the Fourier transform properties, the positiveness of $\mathcal{F}[K]$ and to impose the positive uniform lower bound for the integral of square of $\mathcal{F}[f_{\gamma}]$ in a neighborhood of the origin, which necessarily induces a uniform lower bound for $\int_{\mathbb{R}} f_{\gamma}^2$. Assumptions D-(c)(iii) will complete the sufficient conditions for deriving standard normal critical values using the central limit theorem for U -statistics of Guerre and Lavergne (2005, Lemma 2). To summarize, the choice of β_0 and B_p will be decided in the applications and will also depend on the law of X and the choice of the basis $\mathcal{R}$. In view of our extensive simulation experiment, we argue that the choice of B_p is not an issue in applications, one can confidently perform the optimization on the whole hypersphere $\mathcal{S}^p$. Finally, the condition $B_p \times 0_{p'-p} \subset B_{p'}, \forall p < p'$, is a mild technical condition that combined with Lemma 2.1-(A) greatly simplifies the proof of the consistency of our test.

The first step is the study of the behavior of the process $Q_n(\gamma)$, $\gamma \in B_p$, under H_0 when p is allowed to increase with the sample size.

Lemma 3.1 *Under Assumptions D and K and if H_0 holds true,*

$$\sup_{\gamma \in B_p \subset \mathcal{S}^p} |Q_n(\gamma)| = O_{\mathbb{P}}(n^{-1}h^{-1/2}p^{3/2} \ln n).$$

Moreover, if $\hat{\tau}_n^2(\gamma)$ is the estimate defined in equation (3.5),

$$\sup_{\gamma \in B_p \subset \mathcal{S}^p} \{1/\hat{\tau}_n^2(\gamma)\} = O_{\mathbb{P}}(1).$$

If in addition condition (3.8) holds true, $1/\hat{v}_n^2 = O_{\mathbb{P}}(1)$ with $\hat{v}_n^2$ defined in (3.7).

We now describe the behavior of $\hat{\gamma}_n$ under H_0 . A suitable rate α_n will make $\hat{\gamma}_n$ to be equal to $\gamma_0^{(p)}$ with high probability. Under the null, α_n has to grow to infinity sufficiently

fast to render the probability of the event $\{\hat{\gamma}_n = \gamma_0^{(p)}\}$ close to 1. We will see below that, for better detection of alternative hypothesis, α_n should grow as slow as possible. Indeed, slower rates for α_n will allow the selection of directions $\hat{\gamma}_n$ that could be better suited than $\gamma_0^{(p)}$ for revealing the departure from the null hypothesis. The rate of p is also involved in the search of a trade-off for the rate of α_n : larger p renders slower the rate of uniform convergence to zero of $Q_n(\gamma)$, $\gamma \in B_p$, and hence requires larger α_n .

Lemma 3.2 *Under Assumptions D, K, and condition (3.8) if the variance estimator is the one defined in (3.7), for a positive sequence α_n , $n \geq 1$ such that $\alpha_n/\{p^{3/2} \ln n\} \rightarrow \infty$,*

$$\mathbb{P}(\hat{\gamma}_n = \gamma_0^{(p)}) \rightarrow 1, \quad \text{under } H_0.$$

The following result shows that the asymptotic critical values of our test statistic are standard normal.

Theorem 3.3 *Under the conditions of Lemma 3.2 and if the hypothesis H_0 in (1.1) holds true, the test statistic T_n converges in law to a standard normal. Consequently, the test given by $\mathbb{I}(T_n \geq z_{1-a})$, with z_a the $(1-a)$ -quantile of the standard normal distribution, has asymptotic level a .*

3.4 The behavior under the alternatives

First let us give an intuition on the reason why our test is consistent. Consider the alternative hypothesis

$$H_1 : \mathbb{P}[\mathbb{E}(U \mid X) = 0] < 1.$$

The way the statistic T_n is constructed guarantees the consistency of our test against H_1 . Indeed, we can write

$$\begin{aligned} T_n &= \frac{nh^{1/2}Q_n(\hat{\gamma}_n)}{\hat{v}_n(\hat{\gamma}_n)} \\ &= \max_{\gamma \in B_p} \left\{ nh^{1/2}Q_n(\gamma)/\hat{v}_n(\gamma) - \alpha_n \mathbb{I}_{\{\gamma \neq \gamma_0^{(p)}\}} \right\} + \alpha_n \mathbb{I}_{\{\hat{\gamma}_n \neq \gamma_0^{(p)}\}} \\ &\geq \frac{\max_{\gamma \in B_p} nh^{1/2}Q_n(\gamma)}{\hat{v}_n(\gamma_0^{(p)})} - \alpha_n \geq \frac{nh^{1/2}Q_n(\gamma)}{\hat{v}_n(\gamma_0^{(p)})} - \alpha_n, \quad \forall \gamma \in B_p \subset \mathcal{S}, \end{aligned} \quad (3.9)$$

with $\hat{v}_n(\gamma_0^{(p)})$ equal to $\hat{\tau}_n(\gamma_0^{(p)})$ defined in (3.6) or equal to $\hat{v}_n$ defined in (3.7). Since $\mathbb{E}(U^2 \mid X) \geq \underline{\sigma}^2$ and $\text{Var}(U \mid \langle X, \gamma_0^{(p)} \rangle) \geq \underline{\sigma}^2$, it is clear that $1/\hat{v}_n(\gamma_0^{(p)}) = O_{\mathbb{P}}(1)$ for both variance estimates introduced above. On the other hand, from Lemma 2.1, there exists p_0 and $\tilde{\gamma} \in B_{p_0}$ such that the expectation of $Q_n(\tilde{\gamma})$ stays away from zero as the sample size grows to infinity and h decrease to zero. On the other hand, for any $p > p_0$ and any n and h , clearly $\max_{\gamma \in B_p} Q_n(\gamma) \geq Q_n(\tilde{\gamma})$, because $B_{p_0} \times 0_{p-p_0} \subset B_p$. All these facts show why our test is omnibus, that is consistent against nonparametric alternatives, provided that $p \rightarrow \infty$.

To formalize the consistency result, let us fix some real-valued function $\delta(X)$ such that $\mathbb{E}[\delta(X)] = 0$ and $0 < \mathbb{E}[\delta^4(X)] < \infty$, and some sequence of real numbers r_n that could decrease to zero (the case $r_n \equiv 1$ is also included). Consider the sequence of alternatives

$$H_{1n} : U = U^0 + r_n \delta(X), \quad n \geq 1, \quad \text{with } \mathbb{E}(U^0 | X) = 0. \quad (3.10)$$

We show below that such directional alternatives can be detected as soon as $r_n^2 n h^{1/2} / \alpha_n$ tends to infinity. This is exactly the same condition as in Lavergne and Patilea (2008). However, in the functional data framework, to obtain the convenient standard normal critical values, we need $1/\alpha_n = o(p^{-3/2} \ln^{-1} n)$. Hence, the rate r_n at which the alternatives H_{1n} tend to the null hypothesis should satisfy $r_n^2 n h^{1/2} / \{p^{3/2} \ln n\} \rightarrow \infty$.

Theorem 3.4 *Suppose that*

- (a) *Assumption D holds true with U replaced by U^0 ;*
- (b) *Assumption K is satisfied, and so is the condition (3.8) if the variance estimator is the one defined in (3.7);*
- (c) *$\alpha_n / \{p^{3/2} \ln n\} \rightarrow \infty$ and $r_n, n \geq 1$ is such that $r_n^2 n h^{1/2} / \alpha_n \rightarrow \infty$;*
- (d) *$\mathbb{E}[\delta(X)] = 0$ and $0 < \mathbb{E}[\delta^4(X)] < \infty$.*

Then the test based on T_n is consistent against the sequence of alternatives H_{1n} if there exists $p \geq 1$ and $\tilde{\gamma} \in B_p$ such that $\mathbb{P}(\mathbb{E}[\delta(X) | \langle X, \tilde{\gamma} \rangle] = 0) < 1$ and one of the following conditions is satisfied:

1. *the density $f_{\tilde{\gamma}}$ is bounded;*
2. *the function $\mathbb{E}[\delta(X) | \langle X, \tilde{\gamma} \rangle = \cdot] f_{\tilde{\gamma}}(\cdot)$ is bounded;*
3. *the Fourier transform of $\mathbb{E}[\delta(X) | \langle X, \tilde{\gamma} \rangle = \cdot] f_{\tilde{\gamma}}(\cdot)$ is integrable on $\mathbb{R}$.*

Let us recall that the existence of p and $\tilde{\gamma} \in B_p$ such that $\mathbb{P}[\delta(X) | \langle X, \tilde{\gamma} \rangle] = 0) < 1$ is guaranteed by Lemma 2.1.

4 Testing the goodness-of-fit of parametric models

Here we apply our projection-based testing methodology for testing the goodness-of-fit of the functional linear regression model against *nonparametric* alternatives satisfying mild technical conditions. Hence we provide a simple goodness-of-fit procedure for a widely used model. To the best of our knowledge, our results are completely new in the functional regression framework.

Let U be a real-valued random variable and X be a random variable with values in $L^2[0, 1]$. The model we want to test is the functional linear model defined by

$$Y = a + \langle b, X \rangle + U,$$

where $b \in L^2[0, 1]$ and $a \in \mathbb{R}$ are unknown parameters. The null hypothesis is

$$H_0 : \mathbb{E}(U|X) = 0 \quad \text{a.s.} \quad (4.11)$$

In order to formally establish consistency against nonparametric alternatives, we will consider a sequence of local alternatives like in (3.10).

Like in Assumption D we consider that $(U_1, X_1), \dots, (U_n, X_n)$ are independent copies of (U, X) , but now the observations are $(Y_1, X_1), \dots, (Y_n, X_n)$. Hence the error term U has to be estimated in a preliminary step from the estimates of the parameters a and b . We will investigate the behavior of our test statistic under the null and under the alternatives for a generic estimate of the slope with suitable rate of convergence. Next, we will get into the details in the standard case of the slope estimate based on the functional principal component analysis. In particular, we will see how the difficulty of estimating the parameters in the functional regression model could perturb the properties of test. To keep the technical conditions readable, hereafter we will assume that $\mathbb{E}(|U|^m) < \infty$ for any $m \geq 1$.

4.1 The test statistic and the behavior under the null hypothesis

The test statistic is similar to the one we proposed for testing the effect of a functional covariate. Let $\beta_0, \gamma_0^{(p)}, \mathcal{S}^p$ and B_p be defined as in section 3. Let $\hat{b} \in L^2[0, 1]$ denote a generic estimator of the slope b and let

$$\hat{a} = \bar{Y}_n - \int_0^1 \hat{b}(t) \bar{X}_n(t) dt = a - \int_0^1 \{\hat{b}(t) - b(t)\} \bar{X}_n(t) dt + \bar{U}_n,$$

where $\bar{U}_n = n^{-1} \sum_{i=1}^n U_i$. Let $\hat{U}_i = Y_i - \hat{a} - \langle \hat{b}, X_i \rangle$ be the residuals and let

$$Q_n(\gamma; \hat{a}, \hat{b}) = \frac{1}{n(n-1)} \sum_{1 \leq i \neq j \leq n} \hat{U}_i \hat{U}_j \frac{1}{h} K_h(\langle X_i - X_j, \gamma \rangle), \quad \gamma \in \mathcal{S}^p,$$

where recall $K(\cdot)$ is a kernel, h a bandwidth and $K_h(\cdot) = K(\cdot/h)$. Let $\hat{v}_n^2(\cdot; \hat{a}, \hat{b})$ be an estimate of the variance of $nh^{1/2}Q_n(\cdot; \hat{a}, \hat{b})$ like in section 3.2. Given $B_p \subset \mathcal{S}^p$ with strictly positive Lebesgue measure in $\mathcal{S}^p$ that contains $\gamma_0^{(p)}$, the least favorable direction γ for H_0 is defined as

$$\hat{\gamma}_n = \arg \max_{\gamma \in B_p} \left[nh^{1/2}Q_n(\gamma; \hat{a}, \hat{b}) / \hat{v}_n(\gamma; \hat{a}, \hat{b}) - \alpha_n \mathbb{I}_{\{\gamma \neq \gamma_0^{(p)}\}} \right]. \quad (4.12)$$

The test statistic is then

$$T_n = nh^{1/2} \frac{Q_n(\hat{\gamma}_n; \hat{a}, \hat{b})}{\hat{v}_n(\hat{\gamma}_n; \hat{a}, \hat{b})}. \quad (4.13)$$

We will show that an asymptotic α -level test is given by $\mathbb{I}(T_n \geq z_{1-a})$, where z_a is the $(1-a)$ -quantile of the standard normal distribution.

To derive the standard normal behavior of the test statistic under the null, we will show that under suitable conditions

$$\sup_{\gamma \in \mathcal{S}^p} nh^{1/2} |Q_n(\gamma; \hat{a}, \hat{b}) - Q_n(\gamma)| = o_{\mathbb{P}}(1) \quad \text{and} \quad \sup_{\gamma \in \mathcal{S}^p} |\hat{v}_n(\gamma; \hat{a}, \hat{b}) / \hat{v}_n(\gamma) - 1| = o_{\mathbb{P}}(1), \quad (4.14)$$

with $Q_n(\gamma)$ and $\hat{v}_n(\gamma)$ defined like in section 3, that is we will bring the problem back to the case where the errors U_i are observed.

Lemma 4.1 *Assume the conditions of Theorem 3.3 are met, $\mathbb{E}(|U|^m) < \infty$ for any $m \geq 1$, and $\int_0^1 \mathbb{E}[X^2(t)]dt < \infty$. Let $\hat{b} \in L^2[0, 1]$ be an estimator of b such that $\|\hat{b} - b\|_{L^2} = O_{\mathbb{P}}(n^{-\rho})$ for some $3/8 < \rho \leq 1/2$. Moreover, suppose that the bandwidth h is such that $n^{1-2\zeta}h^{1/2} \rightarrow 0$ for some $3/8 < \zeta < \rho$. Then, under the hypothesis H_0 the uniform rates of convergence in (4.14) holds true.*

At this stage it is worthwhile to notice an important difference between the functional data framework and the finite-dimension case. In the later case the parameters of a parametric regression model could be easily estimated at the usual rate $O_{\mathbb{P}}(n^{-1/2})$ which makes that the equivalences (4.14) to hold without any further conditions on the model. In the functional covariate and functional parameter case, the rate of $\|\hat{b} - b\|$ depends on the regularities of the covariate and of the slope parameter and is in general less than $O_{\mathbb{P}}(n^{-1/2})$, see Hall and Horowitz (2007), Crambes, Kneip and Sarda (2009). To make the differences $\hat{U}_i - U_i$ sufficiently small and hence to preserve the standard normal critical values for T_n defined in (4.13) one has to pay a price on the bandwidth h : slower rates of $\|\hat{b} - b\|_{L^2}$ will require faster decreases for h , and this will result in a loss of power against sequences of local alternatives. Below, we will investigate these aspects in more detail in the case where the slope is estimated using the functional principal component approach.

Theorem 4.2 *Under the conditions of Lemma 4.1 and if the hypothesis H_0 holds true, the law of the test statistic T_n is asymptotically standard normal. Consequently the test given by $\mathbb{I}(T_n \geq z_{1-a})$, where z_a is the $(1-a)$ -quantile of the standard normal distribution, has asymptotic level α .*

The proof of this theorem is a direct consequence of Lemma 4.1 and the arguments we used for Theorem 3.3, therefore we will omit it.

There are several possibilities to estimate the parameters of a functional linear model. Let us investigate our test in the case where the estimate $\hat{b}$ is obtained using the functional principal component analysis (PCA) approach, which is a standard approach for estimating the slope b ; see for instance Ramsay and Silverman (2005) and Hall and Horowitz

(2007). For the sake of completeness, let us briefly recall this estimation procedure. Let $\mathcal{K}(u, v) = \text{Cov}(X(u), X(v))$, $\bar{X}_n = n^{-1} \sum_{i=1}^n X_i$ and

$$\hat{\mathcal{K}}(u, v) = \sum_{i=1}^n (X_i(u) - \bar{X}_n(u))(X_i(v) - \bar{X}_n(v)).$$

Write the spectral expansions of $\mathcal{K}$ and $\hat{\mathcal{K}}$ as

$$\mathcal{K}(u, v) = \sum_{j=1}^{\infty} \theta_j \phi_j(u) \phi_j(v), \quad \hat{\mathcal{K}}(u, v) = \sum_{j=1}^{\infty} \hat{\theta}_j \hat{\phi}_j(u) \hat{\phi}_j(v),$$

where

$$\theta_1 > \theta_2 > \dots > 0, \quad \hat{\theta}_1 \geq \hat{\theta}_2 \geq \dots \geq 0$$

are the eigenvalues sequences of the operators with kernel $\mathcal{K}$ and $\hat{\mathcal{K}}$, respectively, and $\phi_1, \phi_2, \dots$ and $\hat{\phi}_1, \hat{\phi}_2, \dots$ are the respective orthonormal eigenfunctions sequences. The linear operator corresponding to $\mathcal{K}$ is defined by $(\mathcal{K}f)(u) = \int \mathcal{K}(u, v)f(v)dv$. We have $\mathcal{K}b = g$ where $g(u) = \mathbb{E}[(Y - \mathbb{E}(Y))(X(u) - \mathbb{E}(X(u)))]$. This suggests the estimator

$$\hat{b}(t) = \sum_{j=1}^m \hat{b}_j \hat{\phi}_j(t), \quad t \in [0, 1], \quad (4.15)$$

where the truncation point m is a smoothing parameter, $\hat{b}_j = \hat{\theta}_j^{-1} \hat{g}_j$, $\hat{g}_j = \langle \hat{g}, \hat{\phi}_j \rangle$ and

$$\hat{g}(t) = n^{-1} \sum_{i=1}^n (Y_i - \bar{Y}_n)(X_i(t) - \bar{X}_n(t)) \quad (4.16)$$

with $\bar{Y}_n = n^{-1} \sum_{i=1}^n Y_i$.

For simplicity, hereafter the orthonormal basis $\mathcal{R}$ introduced in section 2 is the basis composed of the sequence of orthonormal eigenfunctions $\phi_1, \phi_2, \dots$ of the covariance operator $\mathcal{K}$. Hence $X(t) = \sum_{j=1}^{\infty} x_j \phi_j(t)$, where the random coefficients $x_j = \langle X, \phi_j \rangle$. The following assumptions are standard conditions on the covariance operator $\mathcal{K}$ and the slope parameter in the linear model, as could be found in Hall and Horowitz (2007).

Assumption P

- (a) The covariate X has finite fourth moment, that is $\int_0^1 \mathbb{E}[X^4(t)]dt < \infty$; moreover for some constant $C > 1$, $\mathbb{E}[x_j - \mathbb{E}(x_j)]^4 \leq C\theta_j^2$ for all j .
- (b) The errors U_i are identically distributed, independent of X_i , with zero mean and finite variance.
- (c) The eigenvalues θ_j of the covariance operator $\mathcal{K}$ satisfy

$$\theta_j - \theta_{j+1} \geq C^{-1} j^{-\alpha-1} \quad \forall j \geq 1.$$

(d) The Fourier coefficients b_j satisfy

$$|b_j| \leq Cj^{-\beta}$$

and $\alpha > 1$, $\frac{3}{2}\alpha + 2 < \beta$.

The condition $\frac{3}{2}\alpha + 2 < \beta$ replaces condition $\frac{1}{2}\alpha + 1 < \beta$ of Hall and Horowitz (2007) in order to conciliate the various requirements on the bandwidth h . For comparison, see also Theorem 4.1 of Cai and Hall (2006) where is required $\beta \geq \alpha + 2$. Hall and Horowitz (2007) show if Assumption P hold true and if $m \asymp n^{1/(\alpha+2\beta)}$, then

$$\|\widehat{b} - b\|_{L^2}^2 = O_{\mathbb{P}}\left(n^{-\frac{2\beta-1}{\alpha+2\beta}}\right),$$

and this rate is optimal in a minimax sense. In this case $\rho = (2\beta - 1)/\{2(\alpha + 2\beta)\}$ and the condition $\rho > 3/8$ of Theorem 4.2, which guarantees a non empty range for the bandwidth, becomes $\frac{3}{2}\alpha + 2 < \beta$, that is Assumption P-(d).

4.2 The behavior under the alternatives

The alternatives of the functional linear model we consider are of the form

$$H_{1n} : Y_{in} = a + \langle b, X_i \rangle + r_n \delta(X_i) + U_i^0, \quad n \geq 1, \quad \text{with } \mathbb{E}(U_i^0 | X_i) = 0, \quad 1 \leq i \leq n, \quad (4.17)$$

with $\delta(\cdot)$ an real-valued function such that $0 < \mathbb{E}[\delta^4(X)] < \infty$ and r_n , $n \geq 1$ a sequence of real numbers.

To be able to investigate the behavior of the test statistic under the alternatives, first we have to analyze the behavior of $\widehat{b}$ the estimator of b . To keep the paper at a reasonable length, hereafter we consider that $\widehat{b}$ is estimator obtained through that functional PCA approach. In Lemma 4.3 below we derive the rate of convergence of $\widehat{b}$ towards b under the alternatives H_{1n} , provided that the function $\delta(\cdot)$ satisfies the orthogonality conditions

$$\mathbb{E}[\delta(X)] = 0 \quad \text{and} \quad \mathbb{E}[\delta(X)X] = 0. \quad (4.18)$$

Such orthogonality conditions are quite common in nonparametric testing, see for instance equation (3.11) in Guerre and Lavergne (2005), and they allow to focus on the performance of the test to detect departures from the model.

Lemma 4.3 *Assume that $X_1, \dots, X_n$ are independent draws from X , $\int_0^1 \mathbb{E}[X^2(t)]dt < \infty$ and condition (4.18) hold true. Let $\widehat{b}$ (resp. $\widehat{b}^0$) be the estimator defined in (4.15) obtained from data generated according to the model (4.17) with a bounded sequence $r_n \geq 0$, $n \geq 1$ (resp. with $r_n = 0$ for all $n \geq 1$). Then*

$$\|\widehat{b}^0 - \widehat{b}\|_{L^2}^2 = O_{\mathbb{P}}(r_n^2 n^{-1}) \sum_{j=1}^m \widehat{\theta}_j^{-2}.$$

If in addition assumption P hold true and $m \asymp n^{1/(\alpha+2\beta)}$, then

$$\int_0^1 \{\widehat{b}(t) - b(t)\}^2 dt = O_{\mathbb{P}}\left(n^{-\frac{2\beta-1}{\alpha+2\beta}}\right) + o_{\mathbb{P}}(r_n^2).$$

Let us note that no moment condition for U^0 is needed for the proof of the first part of Lemma 4.3. Moreover, let us point out that we will not need to investigate the convergence rate for the estimator of a under the alternatives since by construction

$$\widehat{a} - a = - \int_0^1 \{\widehat{b}(t) - b(t)\} \overline{X}_n(t) dt + \overline{U}_n.$$

Now, we can analyze the behavior of the test statistics under the alternatives (4.17). The estimated residuals $\widehat{U}_i$ can be decomposed

$$\widehat{U}_i = U_i^0 + r_n \delta(X_i) - \langle \widehat{b} - b, X_i - \overline{X}_n \rangle - r_n \overline{\delta(X)}_n - \overline{U}_n \quad (4.19)$$

Theorem 4.4 *Consider the sequence of alternative hypotheses (4.17) with a nonzero function δ satisfying (4.18) and $0 < \mathbb{E}[\delta^4(X)] < \infty$. Let $\widehat{b} \in L^2[0, 1]$ be an estimator of the slope parameter b . Suppose that the conditions of Theorem 4.2 are met with U replaced by U^0 . Moreover, assume that $\widehat{b}$, the sequence r_n , $n \geq 1$, the sequence α_n , $n \geq 1$ and the bandwidth h satisfy the additional conditions:*

- (i) $r_n^2 n h^{1/2} / \alpha_n \rightarrow \infty$;
- (ii) $r_n^{-1} \|\widehat{b} - b\|_{L^2} = o_{\mathbb{P}}(1)$;
- (iii) $\alpha_n / \{p^{3/2} \ln n\} \rightarrow \infty$.

Then the test based on T_n defined in (4.13) will reject the functional linear regression model with probability tending to 1, provided there exists $p \geq 1$ and $\tilde{\gamma} \in B_p$ such that at least one of conditions (1) to (3) of Theorem 3.4 holds true.

If Assumption P holds true, condition (ii) of Theorem 4.4 indicates that the test could detect only local alternatives H_{1n} that approach the null hypothesis slower than $n^{-(2\beta-1)/\{2(\alpha+2\beta)\}}$. Meanwhile, in order to detect the fastest possible alternatives, the bandwidth should decrease to zero as slow as allowed by condition (i), that is faster than $n^{-2(\alpha+1)/(\alpha+2\beta)}$ times a power of $\ln n$, provided the dimension p and α_n increase as fast as a power of $\ln n$ such that condition (iii) is met.

5 Empirical analysis

5.1 Bootstrap procedures

To improve the critical values of the test statistic T_n with small samples we consider a wild bootstrap procedure that can be applied in both cases we consider herein: the U_i 's are observed or the U 's are estimated by some $\widehat{U}_i$'s. A bootstrap sample is denoted by U_i^b or $\widehat{U}_i^b$, $1 \leq i \leq n$. The wild bootstrap procedure we propose is inspired by Mammen (1993): $U_i^b = Z_i U_i$ (resp. $\widehat{U}_i^b = Z_i \widehat{U}_i$), $1 \leq i \leq n$, with $Z_i = V_i/\sqrt{2} + (V_i^2 - 1)/2$ and V_i independent standard normal variables independent from the original observations. A bootstrap test statistic is built from a bootstrap sample as was the original test statistic. When this scheme is repeated many times, the bootstrap critical value $z_{1-\alpha,n}^*$ at level α is the empirical $(1 - \alpha)$ -th quantile of the bootstrapped test statistics. This critical value is then compared to the initial test statistic.

5.2 Simulation study

An extensive simulation study was carried out. For reasons of brevity, only a summary of the main results and conclusions is given here. We will focus on the goodness-of-fit test of parametric models.

Let us start with the functional linear model, as considered in Section 4, given by

$$Y = a + \langle b, X \rangle + U$$

The function X is drawn as a Brownian motion, $b \in L^2[0, 1]$ and $a \in \mathbb{R}$ are parameters to be estimated, and $U = \delta(X) + U^0$, where $\delta(X)$ is the deviation from the null hypothesis, and U^0 is the error. For the parameters, $b(t) = 1$ for all $t \in [0, 1]$ and $a = 0$ were taken as the true values.

A sample $(Y_1, X_1), \dots, (Y_n, X_n)$ of size $n = 200$ will be drawn from this model, that is,

$$Y_i = a + \langle b, X_i \rangle + \delta(X_i) + U_i^0, \quad 1 \leq i \leq n,$$

where $U_1^0, \dots, U_n^0$ are independent standard normal variables, also independent of the X_i .

The first scenario will be the goodness-of-fit of the functional linear model versus a quadratic type deviation

$$\delta_Q(X) = c \left(\int_0^1 \int_0^1 X(s)X(t) ds dt - 1/3 \right)$$

where $c = 0$ under the null hypothesis and $c = 0.6$ under the alternative. The second scenario will be the goodness-of-fit of the functional linear model versus a cubic deviation

$$\delta_c(X) = d \left(\int_0^1 \int_0^1 \int_0^1 X(s)X(t)X(z) ds dt dz - \int_0^1 X(t)dt \right) \quad (5.20)$$

where $d = 0$ under the null and $d = 0.9$ under the alternative. Note that the two functions $\delta_Q(\cdot)$ and $\delta_c(\cdot)$ satisfy the orthogonality conditions (4.18). In these two scenarios, the PCA estimator of the functional linear model, studied in Hall and Horowitz (2007), is used.

Let us recall that the Karhunen-Loève expansion of the Brownian motion X , is given by

$$X(t) = \sum_{j=1}^{\infty} x_j \frac{1}{(j-0.5)\pi} \sqrt{2} \sin((j-0.5)\pi t)$$

where x_j are independent standard normal coefficients, $\mathcal{R} = \{\rho_j(t) = \sqrt{2} \sin((j-0.5)\pi t) : j \in \{1, 2, \dots\}\}$ constitutes an orthonormal basis of eigenfunctions, and $1/((j-0.5)^2\pi^2)$ are eigenvalues. We made use of this basis $\mathcal{R}$, and took different values of p , the number of basic elements. Other basis were also checked. The role played by the basis and the dimension p consists of allowing to approximate both the covariate function X and the alternative. A good basis is that which provides a good approximation with a small dimension p . The Karhunen-Loève basis is obviously a good basis to approximate the covariate function.

Several possible choices were studied for the privileged direction, $\gamma_0^{(p)}$. Here we present results with an uninformative one, with the same coefficients in all basic elements.

Different values for the penalization were considered. Since the statistic is standardized before penalization, natural values for α_n are 3, 4, 5 or 6. Small values of the penalization provide results that are similar to those obtained with the direction maximizing the standardized statistic, that is, $\arg \max_{\gamma \in \mathcal{S}^p} nh^{1/2} Q_n(\gamma) / \hat{v}_n(\gamma)$, while larger values of the penalization lead to results similar to those obtained with the chosen direction $\gamma_0^{(p)}$. The results presented here correspond to the penalization $\alpha_n = 5$.

To compute the statistic for each direction, we used the Epanechnikov kernel, $K(x) = 1 - x^2$ for $x \in [-1, 1]$. A grid of bandwidths was used in order to explore the effect of the bandwidth on the power of the test.

To estimate the conditional variance, the two estimators (3.5) and (3.7) were considered. For the estimator (3.7), a kernel estimator of the errors' conditional variance was used, with uniform kernel and bandwidth $h_v = 0.5n^{-1/6}$. We observed a better power under the alternative with the estimator (3.7), so the results will be given with this estimator.

For the optimization in the hypersphere $\mathcal{S}^p$, a grid of 300 points was used in the case of $p = 3$ dimensions, and a grid of 1280 points in the case of $p = 5$ dimensions. Additionally, a local refinement of the optimum was used, with 9 points in dimension $p = 3$ and 81 points in dimension $p = 5$. For each original sample, we used 199 bootstrap samples to compute the critical value. One thousand original samples were used to approximate the percentages of rejection. The results shown in figures below were obtained with dimension $p = 3$.

Figure 1 shows the empirical powers obtained for a grid of values of the bandwidth both under the null hypothesis of the functional linear and under the quadratic alternative. We observe that the power is not very much affected by the bandwidth around a possibly optimal value.

For purposes of comparison, the empirical power of the Horvath and Reeder (2011)'s test (HR test for brevity) is also shown. These authors proposed a test of significance of the quadratic effect under a functional quadratic model. Note that HR test is specially designed to detect quadratic alternatives to the linear model, as the one proposed here as the first scenario. As expected, HR test is more powerful than our test, specially for dimension 1. This dimension represents the number of components in the estimation of the functional linear model, which in the case of the HR test coincides with the dimension used in the test statistic to estimate the quadratic deviation. HR test loses power when the dimension increases as a consequence of a bigger noise in the test statistic.

For our test, $m = 3$ was used for the estimation of the functional linear model and $p = 3$ was taken for the number of basic elements. Simulations were also carried out with other values of m and p , and we observed that our test provides similar power when increasing each of these dimensions. The reason is that our test is not very much affected by the noise coming from increasing dimension, and this allows for a bigger dimension and consequently a better approximation of the deviation. It could be said that our test reaches a better trade-off between the noise coming from dimensionality and the approximation of the linear model and the alternative.

Figure 1: Testing the functional linear model versus a quadratic alternative.

Figure 2 shows the power of our test under the second scenario, where a functional linear model is tested versus a cubic alternative. As expected, HR test is not very powerful since it was not designed to detect this kind of alternative. The power of our test is good

in a wide range of values of the bandwidth and the level is very well respected under the null hypothesis.

Figure 2: Testing the functional linear model versus a cubic alternative.

As an illustration of the behavior of our test for the goodness-of-fit of a more general parametric model, we considered the goodness-of-fit of the quadratic functional model, and obtained percentages of rejection under the null hypothesis and under the cubic alternative. That is, the simulated model would be

$$Y = a + \int_0^1 b(t)X(t) dt + \int_0^1 \int_0^1 h(s, t)X(s)X(t) ds dt + \delta(X) + U^0$$

which consists of a quadratic functional model, as considered in Yao and Müller (2010) and Horvath and Reeder (2011), plus a deviation represented by the function $\delta(\cdot)$. Here $b(t) = 1$ for all $t \in [0, 1]$, and $h(s, t) = 0.6$ for all $s, t \in [0, 1]$, which are the same linear and quadratic effects considered before. The deviation was chosen to be $\delta = \delta_c$, that is, the cubic deviation already considered in (5.20). Then, the idea will be to carry out a goodness-of-fit of the functional quadratic model, and evaluate its performance under the null $d = 0$ and under the cubic alternative $d = 0.9$. Results are shown in Figure 3. To the best of our knowledge there is no parametric test for comparison in this situation.

The results show a certain conservative behavior for large bandwidths, while the power is generally good, with no much effect coming from the bandwidths. Results were obtained for different values of p and the dimension of the parametric estimator, with generally good and expectable outcomes. Further investigation will be provided elsewhere.

Figure 3: Testing the functional quadratic model versus a cubic alternative.

5.3 Application to real data

The test proposed here is applied to the data set collected by Tecator and available at <http://lib.stat.cmu.edu/datasets/tecator>. The task is to predict the fat content of a meat sample on the basis of its near infrared absorbance spectrum. For each sample of finely chopped pure meat, a 100 channel spectrum of absorbances was recorded using a Tecator Infratec Food and Feed Analyzer, a spectrometer that works in the wavelength range 850-1050 nm. These absorbances can be thought of as a discrete approximation to the continuous record, $X_i(t)$. Also, for each sample of meat, the fat content, Y_i , was measured by analytic chemistry. The data set contains 240 samples of meat.

Yao and Müller (2010) proposed using a functional quadratic model to predict the fat content, Y_i , of a meat based on its absorbance spectrum, $X_i(t)$. Horvath and Reeder (2011) applied their parametric test to check whether the quadratic term is needed, versus the null hypothesis of a functional linear model. They reached the conclusion that the quadratic effect is significant, and then, the functional quadratic model is needed.

We will apply the test proposed here, first to check the goodness-of-fit of the functional linear model, and later the goodness-of-fit of the functional quadratic model. Table 1 below contains the p-values corresponding to our test for different values of the bandwidth, the parameter m for model estimation and the dimension p . We can conclude that both the functional linear and the functional quadratic models should be rejected for the Tecator data set. This conclusion confirms the empirical results of Chen, Hall and Müller (2011)

who proposed an additive double index model. Indeed, the link functions estimated by Chen, Hall and Müller do not show respective linear and quadratic patterns which indicates that the usual functional linear and the functional quadratic models do not provide a satisfactory fit.

		Linear model				Quadratic model			
	h	0.18	0.30	0.44	0.59	0.18	0.30	0.44	0.59
$p = 2$	$m = 1$	0.5	0.4	0.2	0.6	2.4	1.4	1.6	3.3
	$m = 2$	0.2	0.0	0.0	0.3	0.6	0.3	0.0	0.7

6 Appendix

6.1 Dimension reduction: proof of the fundamental lemma

Proof of Lemma 2.1. (A). The implication $(1) \Rightarrow (2)$ is obvious. To prove $(2) \Rightarrow (1)$, note first that for any $\beta \neq 0$, the σ -field generated by $\langle X, \beta \rangle$ is the same as the σ -field generated by $\langle X, \beta \rangle / \|\beta\|_{L^2}$. Next, by elementary properties of the conditional expectation, we obtain that for any $\beta \in L^2[0, 1]$, including $\beta = 0$,

$$\begin{aligned} 0 &= \mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z \mid \langle X, \beta \rangle)] \\ &= \mathbb{E}[\exp\{i\langle X, \beta \rangle\} Z] \\ &= \mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z \mid X)] . \end{aligned} \tag{6.1}$$

Write $Z = Z^+ - Z^-$ where Z^+ and Z^- are the positive and negative parts of Z , and deduce that for any β , $\mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z^+ \mid X)] = \mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z^- \mid X)]$. As distinct positive finite measures cannot have the same characteristic function, see for instance Theorem 3.1 of Parthasarathy (1967), this implies that $\mathbb{E}(Z^+ \mid X) = \mathbb{E}(Z^- \mid X)$ and hence $\mathbb{E}(Z \mid X) = 0$ almost surely. For $(2) \Rightarrow (3)$ it suffices to identify γ with an element in $L^2[0, 1]$ of norm 1. To prove $(3) \Rightarrow (1)$, fix arbitrarily $\beta \in L^2[0, 1]$, $\beta \neq 0$. For any $p \geq 1$, let $\beta^{(p)}$ be the projection of β on the subspace generated by the first p elements of the basis $\mathcal{R}$. For any p sufficiently large such that $\|\beta^{(p)}\| = \|\beta^{(p)}\|_{L^2} > 0$ we have $\mathbb{E}(Z \mid \langle X, \beta^{(p)} \rangle) = \mathbb{E}(Z \mid \langle X, \beta^{(p)} \rangle / \|\beta^{(p)}\|) = 0$, where for the last equality we use the fact that $\beta^{(p)} / \|\beta^{(p)}\| \in \mathcal{S}^p$ and (3). By elementary properties of the conditional expectation,

$$\begin{aligned} 0 &= \mathbb{E}[\exp\{i\langle X, \beta^{(p)} \rangle\} \mathbb{E}(Z \mid \langle X, \beta^{(p)} \rangle)] \\ &= \mathbb{E}[\exp\{i\langle X, \beta \rangle\} Z \exp\{i\langle X, \beta^{(p)} - \beta \rangle\}] \\ &= \mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z \mid X) [\exp\{i\langle X, \beta^{(p)} - \beta \rangle\} - 1]] \\ &\quad + \mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z \mid X)] . \end{aligned}$$

From the Taylor expansion with integral reminder and elementary calculus, one obtains that $\forall x \in \mathbb{R}$, $|\exp(ix) - 1| \leq \min\{|x|, 2\}$. From this and the Cauchy-Schwarz inequality, deduce that for any p ,

$$|\exp\{i\langle X, \beta^{(p)} - \beta \rangle\} - 1| \leq \min\{\|X\|_{L^2} \|\beta^{(p)} - \beta\|_{L^2}, 2\}.$$

Since $\|\beta^{(p)} - \beta\|_{L^2} \rightarrow 0$ when $p \rightarrow \infty$, by Lebesgue Dominated Convergence Theorem it follows that necessarily

$$\mathbb{E}[\exp\{i\langle X, \beta \rangle\} \mathbb{E}(Z \mid X)] = 0.$$

Since $\beta \in L^2[0, 1]$ was arbitrarily fixed, apply again the arguments we used after equation (6.1) to deduce that (1) hold true. The equivalence $(3) \Leftrightarrow (4)$ follows from Lemma 2.1-(A) of Lavergne and Patilea (2008) applied for each p .

(B). From (A)-4 above, there exists some $p_0 \geq 1$ such that $\mathbb{P}[\mathbb{E}(Z \mid X^{(p_0)}) = 0] < 1$. On the other hand, by the property of iterated expectations, for any $p > p_0$,

$$\mathbb{E}(Z \mid X^{(p_0)}) = \mathbb{E}[\mathbb{E}(Z \mid X^{(p)}) \mid X^{(p_0)}] .$$

Thus necessarily $\mathbb{P}[\mathbb{E}(Z \mid X^{(p)}) = 0] < 1$, $\forall p > p_0$. Fix arbitrarily $p > p_0$ and notice that for any $b \in [-1, 1]$,

$$\{\gamma \in \mathcal{S}^p : \mathbb{E}(Z \mid \langle X, \gamma \rangle) = 0 \text{ a.s.}\} \subset \{\gamma \in \mathcal{S}^p : \mathbb{E}(Z \exp\{b\langle X, \gamma \rangle\}) = 0\}.$$

The expectations in the sets in the last display are well-defined since

$$\mathbb{E}(|Z \exp\{b\langle X, \gamma \rangle\}|) \leq \mathbb{E}(|Z| \exp\{|b|\langle X, \gamma \rangle\}) \leq \mathbb{E}(|Z| \exp\{\|X\|\}) < \infty.$$

Let us notice that

$$\{b\tilde{\gamma} : b \in [-1, 1], \gamma \in \mathcal{S}^p, \mathbb{E}(Z \exp\{b\langle X, \gamma \rangle\}) = 0\} \subset \tilde{A}_p$$

where

$$\tilde{A}_p := \{\tilde{\gamma} \in \mathbb{R}^p : \|\tilde{\gamma}\| \leq 1, \mathbb{E}(Z \exp\{\langle X^{(p)}, \tilde{\gamma} \rangle\}) = 0\}.$$

Thus, to prove (B) it suffice to show that the set $\tilde{A}_p$ has Lebesgue measure zero in $\mathbb{R}^{p-1}$ and is not dense in the unit ball of $\mathbb{R}^{p-1}$.[†]

For these purpose, we will use the following property: if W_1 and W_2 are real-valued random variables such that $\mathbb{E}(|W_1| \exp\{a|W_2|\}) < \infty$ for some $a > 1$, then

$$\mathbb{P}(\mathbb{E}(W_1 \mid W_2) = 0) < 1 \implies \text{the set } \{|b| < a : \mathbb{E}(W_1 \exp\{bW_2\}) = 0\} \text{ is empty or finite.} \quad (6.2)$$

To prove this property, decompose $W_1 = W_1^+ - W_1^-$ and use the positive part W_1^+ to define

$$\lambda^+(b) = \mathbb{E}(W_1^+ \exp\{bW_2\}) = \mathbb{E}(\mathbb{E}(W_1^+ \mid W_2) \exp\{bW_2\}) = \int_{\mathbb{R}} \exp\{bw\} d\mu^+(w),$$

$|b| < a$, where $d\mu^+(w) = \mathbb{E}(W_1^+ \mid W_2 = w) dF_{W_2}(w)$ and F_{W_2} is the probability distribution function of W_2 . Use the negative part of W_1 to define $\lambda^-(b)$, $|b| < a$ similarly. Since W_1 is integrable, $\mu^-(\mathbb{R}), \mu^+(\mathbb{R}) < \infty$. The functions $\lambda^-(\cdot)/\mu^-(\mathbb{R})$ and $\lambda^+(\cdot)/\mu^+(\mathbb{R})$ are the Laplace transforms of the probability distributions $\mu^-/\mu^-(\mathbb{R})$ and $\mu^+/\mu^+(\mathbb{R})$. The condition $\mathbb{E}(|W_1| \exp\{a|W_2|\}) < \infty$ implies that these Laplace transforms, and hence $\lambda^+(\cdot)$ and $\lambda^-(\cdot)$, are (real) analytic on the domain $(-a, a)$. See for instance Proposition 8.4.4 in Chow and Teicher (1997). Notice that the set in (6.2) is the set of $b \in (-a, a)$ for which $\lambda^-(b) = \lambda^+(b)$. If $\mathbb{P}(\mathbb{E}(W_1 \mid W_2) = 0) < 1$, $\lambda^+(\cdot)$ and $\lambda^-(\cdot)$ cannot coincide on $(-a, a)$. Thus the set in (6.2) contains only isolated points b from the interval $(-a, a)$, which means that it is necessarily empty or finite.

Now, recall that we want to investigate the cardinality of the $\tilde{A}_p$, subset of the unit ball of $\mathbb{R}^p$. From (A), there exists $\tilde{\gamma} \in \mathcal{S}^p$ such that $\mathbb{P}(\mathbb{E}(Z \mid \langle X^{(p)}, \tilde{\gamma} \rangle) = 0) < 1$. Then, property (6.2) applied with some $a > 1$, $W_1 = Z$ and $W_2 = \langle X^{(p)}, \tilde{\gamma} \rangle$ implies that the set

$$\{|b| < a : \mathbb{E}(Z \exp\{\langle X^{(p)}, b\tilde{\gamma} \rangle\}) = 0\}$$

[†]An easy way to check that it is indeed sufficient to derive such properties for $\tilde{A}_p$ is to represent the sets in the hyperspherical coordinates.

is empty or finite. Deduce that there exists v^* in the unit ball of $\mathbb{R}^p$, arbitrarily close to the origin, in particular with $\|v^*\| < 1/2$, such that $\mathbb{E}(Z \exp\{\langle X^{(p)}, v^* \rangle\}) \neq 0$. Next, we adapt the lines of the proof of Lemma 1 in Bierens (1990). Let $Z^* = Z \exp\{\langle X^{(p)}, v^* \rangle\}$. By construction, $\mathbb{P}(\mathbb{E}(Z^* | x_1, \dots, x_l) = 0) < 1$, for $l = 1, \dots, p$. Define the sets

$$A_l^* = \{(t_1, \dots, t_l) \in \mathbb{R}^l : \|(t_1, \dots, t_l)\| \leq 3/2, \mathbb{E}(Z^* \exp\{(x_1 t_1 + \dots + x_l t_l)\}) = 0\},$$

$l = 1, \dots, p$. Since $|t_1 x_1 + \langle X^{(p)}, v^* \rangle| \leq \{|t_1| + \|v^*\|\} \|X^{(p)}\| < 2\|X^{(p)}\|$, deduce from property (6.2) applied with $a = 2$, $W_1 = Z$ and $W_2 = \exp\{t_1 x_1 + \langle X^{(p)}, v^* \rangle\}$ that the set A_1^* is empty or finite. Now, define the set

$$A_2^{**}(t_1) = \{|t_2| \leq 3/2 : \mathbb{E}(Z^* \exp\{x_1 t_1\} \exp\{x_2 t_2\}) = 0\}.$$

If $t_1 \notin A_1^*$, replace Z^* by $Z^* \exp\{x_1 t_1\}$ and use again property (6.2) with $a = 7/2$, $W_1 = Z$ and $W_2 = \exp\{t_1 x_1 + t_2 x_2 + \langle X^{(p)}, v^* \rangle\}$ to deduce that the set $A_2^{**}(t_1)$ is empty or finite. This means that A_2^* is contained in the union of some sets $B' \times \mathbb{R}$ and $\mathbb{R} \times B''$ where B' and B'' are empty or finite. Repeat the arguments with $l = 3, \dots, p$ and deduce that A_p^* has Lebesgue measure zero in $\mathbb{R}^p$. Since the norm of v^* could be taken arbitrarily small such that $\tilde{A}_p \subset A_p^*$, we can now easily deduce that $\tilde{A}_p$ has Lebesgue measure zero in the unit ball of $\mathbb{R}^p$. The fact that $\tilde{A}_p$ is not dense in the unit ball of $\mathbb{R}^p$ is a direct consequence of the fact that A_p^* intersected with unit ball of $\mathbb{R}^p$ is not dense. ■

6.2 Rates of convergence: technical lemmas

For ν a probability measure on a sample space, $\mathcal{F}$ a class of functions and $\varepsilon > 0$, let $N(\varepsilon, \mathcal{F}, L^2(\nu))$, denote the covering number, that is the minimal number of balls of radius ε in $L^2(\nu)$ needed to cover $\mathcal{F}$. See Van der Vaart and Wellner (1996) or Kosorok (2008) for the definitions. For real random variables, $A_n \asymp_{\mathbb{P}} B_n$ means that there exists a constant $C > 1$ such that $\mathbb{P}(1/C \leq A_n/B_n \leq C)$ goes to 1 when n grows. In the following $C, C_1, c, c_1, \dots$ represent constants that may change from line to line.

Lemma 6.1 *For any $p \geq 1$, let*

$$\mathcal{F}_{1p} = \{(v_1, v_2) \mapsto K(h^{-1}\langle v_1 - v_2, \gamma \rangle) : v_1, v_2 \in \mathbb{R}^p, \gamma \in \mathcal{S}^p, h > 0\}$$

and

$$\mathcal{F}_{2p} = \{v \mapsto \mathbb{E}[K(h^{-1}\langle X - v, \gamma \rangle)] : v \in \mathbb{R}^p, \gamma \in \mathcal{S}^p, h > 0\}.$$

If Assumption K-(a) holds, there exist constants $c_1, c_2, c_3 > 0$ such that for any $p \geq 1$ and $0 < \varepsilon < 1$ and any ν_1 probability measure on $\mathbb{R}^p \times \mathbb{R}^p$ and ν_2 probability measure on $\mathbb{R}^p$,

$$N(\varepsilon, \mathcal{F}_{jp}, L^2(\nu_j)) \leq c_1(c_2/\varepsilon)^{c_3 p}, \quad j = 1, 2. \quad (6.3)$$

Proof. Since K can be written as a difference of two monotone functions, the result for $\mathcal{F}_{1p}$ is an easy consequence of the Theorem 9.3, Lemmas 9.6 and 9.9 of Kosorok (2008) and Lemma 16 of Nolan and Pollard (1987); see also their Lemma 22-(ii). For $\mathcal{F}_{2p}$, use the bound for $\mathcal{F}_{1p}$ and Lemma 20 of Nolan and Pollard (1987). ■

Lemma 6.2 *Let Assumptions D and K hold true and let l be some strictly positive integer. For each n and p that may depend on n , define the U -processes*

$$V_n^{(k_1, k_2)}(\gamma; l) = \frac{1}{n(n-1)h} \sum_{1 \leq i \neq j \leq n} U_i^{k_1} U_j^{k_2} K_h^l(\langle X_i - X_j, \gamma \rangle), \quad \gamma \in B_p, \quad k_1, k_2 \in \{0, 2\}.$$

Then

$$\sup_{\gamma \in B_p} |V_n^{(0,0)}(\gamma; l)| \asymp_{\mathbb{P}} 1, \quad \sup_{\gamma \in B_p} \{1/|V_n^{(2,2)}(\gamma; l)|\} = O_{\mathbb{P}}(1) \quad \text{and} \quad \sup_{\gamma \in B_p} |V_n^{(2,0)}(\gamma; l)| = O_{\mathbb{P}}(1).$$

Proof. To simplify the writings, we write $V_n^{(0)}$ (resp. $V_n^{(2)}$) instead of $V_n^{(0,0)}$ (resp. $V_n^{(2,2)}$). First consider the case $k_1 = k_2 = 0$. Hoeffding's decomposition allows us to decompose the centered U -processes $hV_n^{(0)}(\gamma; l) - \mathbb{E}[hV_n^{(0)}(\gamma; l)]$ as a sum of two degenerate U -processes $V_{1n}^{(0)}(\gamma; l)$ and $V_{2n}^{(0)}(\gamma; l)$, $\gamma \in B_p$, of respective orders 1 and 2 that are indexed by families of functions obtained by finite sums of sets like $\mathcal{F}_{1p}$ and $\mathcal{F}_{2p}$ in Lemma 6.1 above. By Lemma 16 of Nolan and Pollard (1987), deduce that the families indexing $V_{1n}^{(0)}(\gamma; l)$ and $V_{2n}^{(0)}(\gamma; l)$ are families with covering numbers bounded by polynomials in $1/\varepsilon$ with coefficient and order depending on c_1 , c_2 and c_3 but independent of n and p . (When $l > 1$, K should be replaced by K^l in the definitions of $\mathcal{F}_{1p}$ and $\mathcal{F}_{2p}$, but given the properties of $K(\cdot)$ this has no impact on the conclusion.) Next, by Theorem 2 of Major (2006), $\sup_{\gamma \in B_p} |V_{2n}^{(0)}(\gamma; l)| = O_{\mathbb{P}}(n^{-1}h^{1/2}p^{3/2} \ln n)$; see the proof of our Lemma 3.1 for an example of application of the result of Major (2006). On the other hand, by Theorem 2.14.1 or Theorem 2.14.9 of van der Vaart and Wellner (1996), we have $\sup_{\gamma \in B_p} |V_{1n}^{(0)}(\gamma; l)| = O_{\mathbb{P}}(n^{-1/2}p^{1/2})$. Gathering the rates and using Assumption K-(b,c) we deduce that $V_n^{(0)}(\gamma; l) - \mathbb{E}[V_n^{(0)}(\gamma; l)] = o_{\mathbb{P}}(1)$, uniformly in $\gamma \in B_p$. Now, it remains to show that there exist constants $c_1, c_2 > 0$ such that $c_1 \leq \mathbb{E}[V_n^{(0)}(\gamma; l)] = \mathbb{E}[h^{-1}K_h^l(\langle X_1 - X_2, \gamma \rangle)] \leq c_2$, $\forall \gamma \in B_p$ and h sufficiently small. Using the properties of the Fourier and inverse Fourier transforms, Fubini theorem, the independence of X_1 and X_2 and Plancherel theorem

$$\begin{aligned} \mathbb{E}[h^{-1}K_h^l(\langle X_1 - X_2, \gamma \rangle)] &= (2\pi)^{-1/2} \mathbb{E} \int_{\mathbb{R}} \exp\{it\langle X_1, \gamma \rangle\} \exp\{-it\langle X_2, \gamma \rangle\} \mathcal{F}[K^l](t) dt \\ &= (2\pi)^{1/2} \int_{\mathbb{R}} |\mathcal{F}[f_{\gamma}](t)|^2 \mathcal{F}[K^l](ht) dt \\ &\leq (2\pi)^{1/2} \int_{\mathbb{R}} |\mathcal{F}[f_{\gamma}](t)|^2 dt = (2\pi)^{1/2} \int_{\mathbb{R}} f_{\gamma}^2(x) dx. \end{aligned} \quad (6.4)$$

Assumption D-(c)(i) guarantees that $\mathbb{E}[h^{-1}K_h^l(\langle X_1 - X_2, \gamma \rangle)]$ is uniformly bounded from above. On the other hand, using the positiveness of $\mathcal{F}[K]$ (hence of $\mathcal{F}[K^l]$), the fact that $\mathcal{F}[K^l]$ is necessarily bounded away from zero on compact intervals, the previous display and Assumption D-(c)(ii), deduce that there exists constants c_3 and c_4 such that $\forall p \geq 1$, $\forall \gamma \in B_p$ and $\forall h \leq 1$ (say),

$$\mathbb{E}[h^{-1}K_h^l(\langle X_1 - X_2, \gamma \rangle)] \geq c_3 \int_{|t| \leq \epsilon} |\mathcal{F}[f_{\gamma}](t)|^2 dt \geq c_4 > 0.$$

In the case $k_1 = k_2 = 2$, by Assumption D-(b), $\mathbb{E}(V_n^{(2)}(\gamma; l)) \geq \underline{\sigma}^4 \mathbb{E}[h^{-1} K_h^l(\langle X_1 - X_2, \gamma \rangle)]$, $\forall \gamma$. Next use again Hoeffding's decomposition for $V_n^{(2)}(\gamma; l) - \mathbb{E}(V_n^{(2)}(\gamma; l))$. The degenerate U -statistics of order 1 and 2 can be treated with the same arguments as above. Deduce that $1/V_n^{(2)}(\gamma; l)$ is uniformly bounded in probability. The case $k_1 = 0$ and $k_2 = 2$ could be handled with similar arguments. ■

Lemma 6.3 *Under the conditions of Lemma 4.1, for any $\epsilon > 0$,*

$$\sup_{\gamma \in \mathcal{S}^p, t \in \mathbb{R}} \left| \frac{1}{n} \sum_{i=1}^n U_i K_h(\langle X_i, \gamma \rangle - t) \right| = O_{\mathbb{P}}(p^{1/2} n^{-1/2+\epsilon} h^{1/2}). \quad (6.5)$$

Moreover, there exists $a > 0$ such that for any $\epsilon > 0$,

$$\sup_{\gamma \in B_p} \left| \frac{1}{n(n-1)h} \sum_{1 \leq i \neq j \leq n} U_i K_h(\langle X_i - X_j, \gamma \rangle) \right| = O_{\mathbb{P}}(p^{1/2} n^{-1/2+\epsilon} h^{-1/2+a}). \quad (6.6)$$

Proof. Let $\mathcal{G}$ be a family of functions $|g| \leq 1$ with covering number bounded by $(K/\epsilon)^V$. With the notation of van der Vaart and Wellner (1996), let $\mathbb{G}_n g$, $g \in \mathcal{G}$ be the empirical process indexed by $\mathcal{G}$ and let $\|\mathbb{G}_n\|_{\mathcal{G}} = \sup_{g \in \mathcal{G}} |\mathbb{G}_n g|$. From Theorem 2.14.16 of van der Vaart and Wellner, after tracing the constants in the proof, there exists $C > 0$ independent of n and p such that for any $\delta > 0$, $\exists C_{\delta} > 0$ independent of n and p such that

$$\mathbb{P}(\|\mathbb{G}_n\|_{\mathcal{G}} > t) \leq C \left(\frac{C_{\delta}}{\sigma} \right)^{2V} \left(1 \vee \frac{t}{\sigma} \right)^{3V+\delta} \exp \left\{ -\frac{1}{2} \frac{t^2}{\sigma^2 + (3+t)/\sqrt{n}} \right\} \quad (6.7)$$

for every $t > 0$ and every $\sup_{\mathcal{G}} \text{Var}(g) \leq \sigma^2 \leq 1$. Fix an arbitrary $\epsilon > 0$, use the covering number of $\mathcal{F}_{1p}$ in Lemma 6.1 and apply this inequality with $g(U, X) = n^{-\epsilon/2} U \mathbb{I}(|U| \leq n^{\epsilon/2}) K_h(\langle X, \gamma \rangle - t)$, $\sigma = ch^{1/2}$ and $t = \tilde{t} p^{1/2} n^{-\epsilon/2} \ln^{1/2} n$. Next derive the rate of the reminder $n^{-1} \sum_{i=1}^n U_i (|U| > n^{\epsilon/2}) K_h(\langle X_i, \gamma \rangle - t)$ taking absolute values, recalling that $\mathbb{E}(|U|^m) < \infty$ for every $m \geq 1$, and using Markov inequality. For the second quantity, apply the Hoeffding decomposition to the second order U -statistics defined by $h(U_i, X_i, U_j, X_j) = n^{-\epsilon/2} U_i \mathbb{I}(|U_i| \leq n^{\epsilon/2}) K_h(\langle X_i - X_j, \gamma \rangle)$. For the degenerate U -statistics of order 2 multiply by h and proceed like in Lemma 3.1. To apply inequality (6.7) for the empirical process in Hoeffding decomposition we need a bound for the variance of the conditional expectation $\mathbb{E}[h^{-1} K_h(\langle X_i - X_j, \gamma \rangle) | X_i]$. Let $\delta > 0$ such that $\int_{\mathbb{R}} f_{\gamma}^{2+\delta} \leq C$, $\forall \gamma \in B_p$, for some constant C . By a change of variables, the boundedness of K , Jensen inequality, and again a change of variables we have for some constant C' ,

$$\begin{aligned} \mathbb{E}\{\mathbb{E}^2[h^{-1} K_h(\langle X_i - X_j, \gamma \rangle) | X_i]\} &= \int_{\mathbb{R}} \left[\int_{\mathbb{R}} f_{\gamma}(u - th) K(t) dt \right]^2 f_{\gamma}(u) du \\ &\leq \int_{\mathbb{R}} \left(\int_{\mathbb{R}} f_{\gamma}^{2+\delta}(u - th) dt \right)^{2/(2+\delta)} f_{\gamma}(u) du \\ &\leq C' h^{-2/(2+\delta)}. \end{aligned}$$

Use the covering number of $\mathcal{F}_{2p}$ in Lemma 6.1 and inequality (6.7) to deduce

$$\sup_{\gamma \in B_p} \left| \frac{1}{n} \sum_{1 \leq i \leq n} U_i \mathbb{I}(|U_i| \leq n^{\epsilon/2}) \mathbb{E} [h^{-1} K_h(\langle X_i - X_j, \gamma \rangle) | X_i] \right| = O_{\mathbb{P}}(p^{1/2} h^{-1/(2+\delta)} n^{-1/2+\epsilon/2} \ln^{1/2} n).$$

Use Markov inequality to bound $n^{-1} \sum_{i=1}^n U_i (|U| > n^{\epsilon/2}) \mathbb{E}[h^{-1} K_h(\langle X_i - X_j, \gamma \rangle) | X_i]$ and hence complete the proof. ■

6.3 Testing for no-effect: proofs of the asymptotic results

Let

$$v_n^2(\gamma_0^{(p)}) = \frac{2}{n(n-1)h} \sum_{j \neq i} \sigma_{\gamma_0^{(p)}}^2(\langle X_j, \gamma_0^{(p)} \rangle) \sigma_{\gamma_0^{(p)}}^2(\langle X_j, \gamma_0^{(p)} \rangle) K_h^2(\langle X_i - X_j, \gamma_0^{(p)} \rangle). \quad (6.8)$$

Lemma 6.4 *Let Assumptions D, K and hypothesis H_0 hold true. Then $\hat{\tau}_n^2(\gamma_0^{(p)}) = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\} = v_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$. Moreover, $\hat{v}_n^2 = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$, with $\hat{v}_n^2$ defined in (3.7), provided that condition (3.8) holds true.*

Proof. First let us notice that for any n and any V_{1i}, V_{2i} , $1 \leq i \leq n$, a set of i.i.d. random variables with $\mathbb{E}(V_{1i}^2 + V_{2i}^2) < \infty$ and

$$A_n = \frac{1}{n(n-1)h} \sum_{1 \leq i \neq j \leq n} V_{1i} V_{2j} K(h^{-1} \langle X_i - X_j, \gamma_0^{(p)} \rangle),$$

there exists some constant C (independent of n) such that

$$\begin{aligned} \text{Var}(A_n) &\leq \frac{C}{n} \text{Var}(V_{1i} V_{2j} h^{-1} K(h^{-1} \langle X_i - X_j, \gamma_0^{(p)} \rangle)) \\ &\leq \frac{C}{nh^2} \mathbb{E}[\zeta_1^2(\langle X_i, \gamma_0^{(p)} \rangle) \zeta_2^2(\langle X_j, \gamma_0^{(p)} \rangle) K^2(h^{-1} \langle X_i - X_j, \gamma_0^{(p)} \rangle)] \\ &\leq \frac{C}{nh^2} \mathbb{E}[\zeta_1^2(\langle X_i, \gamma_0^{(p)} \rangle)] \mathbb{E}[\zeta_2^2(\langle X_j, \gamma_0^{(p)} \rangle)] = \frac{C}{nh^2} \mathbb{E}(V_{1i}^2) \mathbb{E}(V_{2i}^2) \end{aligned} \quad (6.9)$$

where $\zeta_l^2(\langle X_i, \gamma_0^{(p)} \rangle) = \mathbb{E}(V_{li}^2 | \langle X_i, \gamma_0^{(p)} \rangle)$, $l = 1, 2$. Since $nh^2 \rightarrow \infty$, we have $\text{Var}(A_n) \rightarrow 0$.

Now, to check $\hat{\tau}_n^2(\gamma_0^{(p)}) = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$ take $V_{1i} = V_{2i} = U_i^2$. We have $\mathbb{E}[\hat{\tau}_n^2(\gamma_0^{(p)}) | X_1, \dots, X_n] = \tau_n^2(\gamma_0^{(p)})$ and

$$\mathbb{E}\{\hat{\tau}_n^2(\gamma_0^{(p)}) - \tau_n^2(\gamma_0^{(p)})\}^2 = \mathbb{E}\{\text{Var}[\hat{\tau}_n^2(\gamma_0^{(p)}) | X_1, \dots, X_n]\} \leq \text{Var}(\hat{\tau}_n^2(\gamma_0^{(p)})) \rightarrow 0. \quad (6.10)$$

By the fact that $\text{Var}(U | X^{(p)})$ is bounded and bounded away from zero almost surely, and the fact that for $l = 2$ and $l = 4$, $\mathbb{E}[h^{-1} K_h^l(\langle X_1 - X_2, \gamma \rangle)]$ is bounded and bounded away from zero $\forall p \geq 1$, $\forall \gamma \in B_p$ and $\forall h \leq 1$, deduce that the expectation of $\tau_n^2(\gamma_0^{(p)})$ stays away from zero and infinity and its variance tends to zero. This together with (6.10)

allow to conclude that $\widehat{\tau}_n^2(\gamma_0^{(p)}) = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$. To obtain the same conclusion with $\tau_n^2(\gamma_0^{(p)})$ replaced by $v_n^2(\gamma_0^{(p)})$ it suffices to consider above conditional expectations given $\langle X_1, \gamma_0^{(p)} \rangle, \dots, \langle X_n, \gamma_0^{(p)} \rangle$. The arguments for $\widehat{v}_n^2$ are similar and hence will be omitted. ■

Proof of Lemma 3.1. Let $M > 0$ be a real number that depend on n in a way that will be specified later, define $\eta_i^M = U_i \mathbb{I}(|U_i| \leq M) - \mathbb{E}(U_i \mathbb{I}(|U_i| \leq M) \mid X_i^{(p)})$ and consider the degenerate U -process

$$U_n \widetilde{g} = \frac{1}{n(n-1)} \sum_{j \neq i} \eta_i^M \eta_j^M K_h(\langle X_i - X_j, \gamma \rangle) = \frac{1}{n(n-1)} \sum_{j \neq i} \widetilde{g}((\eta_i^M, X_i), (\eta_j^M, X_j); h, \gamma)$$

defined by the functions $\widetilde{g}$ indexed by h and $\gamma \in \mathcal{S}^p$. By Assumption D and K-(a), the arguments used in Lemma 6.1 above for the class $\mathcal{F}_{1p}$, and Lemma 9.9-(vi) of Kosorok (2008), the bounded family $\mathcal{F}_{3p} = \{\widetilde{g} : \gamma \in \mathcal{S}^p, h > 0\}$ has a covering number like in (6.3). By Theorem 2 of Major (2006) and its corollary, where we assume without loss of generality that $0 \leq K(\cdot) \leq 1$,

$$\begin{aligned} \mathbb{P}\left(\sup_{\gamma \in \mathcal{S}^p} |U_n \widetilde{g}| \geq \frac{th^{1/2} \ln np^{3/2}}{(n-1)}\right) &= \mathbb{P}\left(\sup_{\gamma \in \mathcal{S}^p} \left| \frac{1}{n} \sum_{j \neq i} \frac{\eta_i^M}{M} \frac{\eta_j^M}{M} K_h(\langle X_i - X_j, \gamma \rangle) \right| \geq \frac{th^{1/2} p^{3/2} \ln n}{M^2}\right) \\ &\leq C_1 C_2 \exp\left\{-C_3 \left(\frac{th^{1/2} p^{3/2} \ln n}{M^2 \sigma_M}\right)\right\}, \quad \text{for any } t > 0, \end{aligned}$$

$$\text{provided} \quad n\sigma_M^2 \geq \frac{th^{1/2} p^{3/2} \ln n}{M^2 \sigma_M} \geq C_4 [p + \max(\ln C_2 / \ln n, 0)]^{3/2} \ln \frac{2}{\sigma_M} \quad (6.11)$$

where $C_1, \dots, C_4 > 0$ are some constants independent on n , h and M and

$$\sigma_M^2 = \sup_{\gamma \in \mathcal{S}^p} \mathbb{E} \left[\left(\frac{\eta_i^M}{M} \right)^2 \left(\frac{\eta_j^M}{M} \right)^2 K_h^2(\langle X_i - X_j, \gamma \rangle) \right].$$

From Assumption D-(b,c) and using the arguments as in the last part of the proof of Lemma 6.2 above, there is a constant $C > 0$ independent of n such that $C^{-1} \leq \sigma_M^2 M^4 / h \leq C$. Take $M^4 = nh p^{-3/2} \ln^{-(1+\delta)} n \rightarrow \infty$ with $\delta > 0$ arbitrarily small. Hence σ_M^2 is of order $n^{-1} p^{3/2} \ln^{1+\delta} n \rightarrow 0$ and for any $t > 0$

$$n\sigma_M^2 \geq \frac{nh}{CM^4} = C^{-1} p^{3/2} \ln^{1+\delta} n \geq \frac{th^{1/2} p^{3/2} \ln n}{M^2 \sigma_M} \quad (6.12)$$

provided n is large enough. On the other hand, for any constant $C' > 0$

$$\frac{th^{1/2} p^{3/2} \ln n}{M^2 \sigma_M} \geq C^{-1/2} t p^{3/2} \ln n \geq C' p^{3/2} \ln n \rightarrow \infty \quad (6.13)$$

for any sufficiently large t . Since $(\ln n)^{-1} \ln(2/\sigma_M)$ is bounded by a positive constant as n goes to ∞ , Equations (6.12) and (6.13) show that (6.11) is satisfied for our M , with n and t large enough. By Theorem 2 of Major (2006), $U_n \tilde{g} = O_{\mathbb{P}}(n^{-1} h^{1/2} p^{3/2} \ln n)$.

Now, it remains to study the tails of U_i , that is we have to derive the orders of the remainder terms

$$2R_{1n} + R_{2n} = \frac{2}{n(n-1)} \sum_{j \neq i} \eta_i^M \xi_j K_h(\langle X_i - X_j, \gamma \rangle) + \frac{1}{n(n-1)} \sum_{j \neq i} \xi_i \xi_j K_h(\langle X_i - X_j, \gamma \rangle)$$

where $\xi_i = U_i - \eta_i^M = U_i \mathbb{I}(|U_i| > M) - \mathbb{E}[U_i \mathbb{I}(|U_i| > M) | X_i]$. Now, $\mathbb{E}[\sup_{\gamma} |R_{1n}|] \leq C \mathbb{E}(|\eta_i^M| |\xi_j|) \leq 2C \mathbb{E}(|U_i|) \mathbb{E}(|\xi_j|) \leq C' \mathbb{E}(|\xi_j|)$, and thus by Hölder's and Chebyshev's inequalities

$$\mathbb{E}(|\xi_i|) \leq 2\mathbb{E}[|U_i| \mathbb{I}(|U_i| > M)] \leq 2\mathbb{E}^{1/m}[|U_i|^m] \mathbb{P}^{(m-1)/m}[|U_i| > M] \leq 2\mathbb{E}[|U_i|^m] M^{1-m}.$$

Now it remains to choose m sufficiently large such that $M^{1-m} = o(n^{-1} h^{1/2} p^{3/2} \ln n)$. With Assumption K-(b) and our choice of M , $m > 11$ will be sufficient. Also it is clear that $\sup_{\gamma} |R_{2n}|$ is of smaller order than $\sup_{\gamma} |R_{1n}|$.

To prove that the inverse of the variance estimate is bounded in probability, in view of Lemma 6.4, it remains to show that $1/\tau_n^2(\gamma)$, $\gamma \in B_p$, is uniformly bounded in probability. For this recall that $\sigma_p^2(X^{(p)}) \geq \underline{\sigma}^2$ and apply Lemma 6.2. Now the proof is complete. ■

Proof of Lemma 3.2. By definition, $nh^{1/2} Q_n(\gamma_0^{(p)})/\widehat{v}_n(\gamma_0^{(p)}) \leq nh^{1/2} Q_n(\widehat{\gamma}_n)/\widehat{v}_n(\widehat{\gamma}_n) - \alpha_n \mathbb{I}(\widehat{\gamma}_n \neq \gamma_0^{(p)})$. This implies that

$$0 \leq \mathbb{I}(\widehat{\gamma}_n \neq \gamma_0^{(p)}) \leq nh^{1/2} \alpha_n^{-1} \left\{ Q_n(\widehat{\gamma}_n)/\widehat{v}_n(\widehat{\gamma}_n) - Q_n(\gamma_0^{(p)})/\widehat{v}_n(\gamma_0^{(p)}) \right\}.$$

From Lemmas 3.1, 6.2 and 6.4,

$$\begin{aligned} \left| \frac{Q_n(\widehat{\gamma}_n)}{\widehat{v}_n(\widehat{\gamma}_n)} - \frac{Q_n(\gamma_0^{(p)})}{\widehat{v}_n(\gamma_0^{(p)})} \right| &\leq 2 \max \left[\sup_{\gamma \in B_p} \{1/\widehat{\tau}_n^2(\gamma)\}, 1/\widehat{v}_n^2 \right] \sup_{\gamma \in B_p} |Q_n(\gamma)| \\ &= O_{\mathbb{P}}(n^{-1} h^{-1/2} p^{3/2} \ln n). \end{aligned}$$

Then $\alpha_n p^{-3/2} / \ln n \rightarrow \infty$ yields $\mathbb{I}(\widehat{\gamma}_n \neq \gamma_0^{(p)}) = o_{\mathbb{P}}(1)$. Thus $\mathbb{P}(\widehat{\gamma}_n \neq \gamma_0^{(p)}) = \mathbb{E}[\mathbb{I}(\widehat{\gamma}_n \neq \gamma_0^{(p)})] \rightarrow 0$. ■

Proof of Theorem 3.3. From Lemma 3.2, the probabilities of the events $\{Q_n(\widehat{\gamma}_n) = Q_n(\gamma_0^{(p)})\}$ and $\{\widehat{v}_n^2(\widehat{\gamma}_n) = \widehat{\tau}_n^2(\gamma_0^{(p)})\}$, with $\widehat{v}_n^2(\cdot)$ defined in (3.6), both converge to 1. On the other hand, by Lemma 6.4 above $\widehat{\tau}_n^2(\gamma_0^{(p)}) = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$. Moreover, $\widehat{v}_n^2 = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$, with $\widehat{v}_n^2$ defined in (3.7), provided that condition (3.8) holds true. Hence it suffices to derive the asymptotic distribution of $nh^{1/2} Q_n(\gamma_0^{(p)})/\tau_n(\gamma_0^{(p)})$ under H_0 . For this purpose we use Assumption D-(c)(iii) and proceed like in Theorem 3.3 and Lemma 6.2 of Patilea and Lavergne (2008); see also the CLT in Lemma 2 of Guerre and Lavergne

(2005). Moreover we use our Lemma 6.2 with $k_1 = k_2 = 0$ and $l = 2$. To be exactly in the case of Lavergne and Patilea (2008), first consider $nh^{1/2}Q_n(\gamma_0^{(p)})/v_n(\gamma_0^{(p)})$ with $v_n(\gamma_0^{(p)})$ defined in (6.8). The arguments for the asymptotic normality of $nh^{1/2}Q_n(\gamma_0^{(p)})/v_n(\gamma_0^{(p)})$ are identical to those of Lavergne and Patilea and hence will be omitted. Finally, by Lemma 6.4, $v_n^2(\gamma_0^{(p)}) = \tau_n^2(\gamma_0^{(p)})\{1 + o_{\mathbb{P}}(1)\}$ and the stated result follows. ■

Proof of Theorem 3.4. The proof is based on inequality (3.9). Since $\mathbb{E}(U^2 \mid X) \geq \underline{\sigma}^2 + r_n^2 \delta^2(X)$, $\mathbb{E}(U \mid X) = r_n \delta(X)$, and $\text{Var}(U \mid \langle X, \gamma_0^{(p)} \rangle) \geq \underline{\sigma}^2 + r_n^2 \text{Var}(\delta(X) \mid \langle X, \gamma_0^{(p)} \rangle)$, clearly the variance estimate $\hat{v}_n(\gamma_0^{(p)})$ stays away from zero. Hence it suffices to look at the behavior of $Q_n(\gamma)$. By Lemma 2.1-(B) there exists p_0 and $\tilde{\gamma} \in B_{p_0} \subset \mathcal{S}^{p_0}$ (p_0 and $\tilde{\gamma}$ independent of n) such that $\mathbb{E}[\delta(X) \mid \langle X, \tilde{\gamma} \rangle] \neq 0$. Since $\max_{\gamma \in B_p} Q_n(\gamma) \geq Q_n(\tilde{\gamma})$ for any $p \geq p_0$, it suffices to investigate the rate of $Q_n(\tilde{\gamma})$. We can write

$$\begin{aligned} Q_n(\tilde{\gamma}) &= \frac{1}{n(n-1)h} \sum_{i \neq j} U_i^0 U_j^0 K_h(\langle X_i - X_j, \tilde{\gamma} \rangle) \\ &\quad + \frac{2r_n}{n(n-1)h} \sum_{i \neq j} U_i^0 \delta(X_j) K_h(\langle X_i - X_j, \tilde{\gamma} \rangle) \\ &\quad + \frac{r_n^2}{n(n-1)h} \sum_{i \neq j} \delta(X_i) \delta(X_j) K_h(\langle X_i - X_j, \tilde{\gamma} \rangle) \\ &=: Q_{0n}(\tilde{\gamma}) + 2r_n Q_{1n}(\tilde{\gamma}) + r_n^2 Q_{2n}(\tilde{\gamma}). \end{aligned}$$

Since $\tilde{\gamma}$ is fixed (and of finite dimension), $Q_{0n}(\tilde{\gamma}) = O_{\mathbb{P}}(n^{-1}h^{-1/2})$ (cf. proof of Theorem 3.3). The U -statistic $Q_{1n}(\tilde{\gamma})$ can be decomposed in a degenerate U -statistic of order 2 with the rate $O_{\mathbb{P}}(h^{-1}n^{-1}) = O_{\mathbb{P}}(n^{-1/2})$ and the sum average of centered variables

$$\frac{1}{n} \sum_{1 \leq i \leq n} U_i^0 \mathbb{E}[\delta(X_j) h^{-1} K_h(\langle X_i - X_j, \tilde{\gamma} \rangle) \mid X_i].$$

Hence it suffice to bound $v_n^2 = \mathbb{E}\{(U_i^0)^2 \mathbb{E}^2[\delta(X_j) h^{-1} K_h(\langle X_i - X_j, \tilde{\gamma} \rangle) \mid X_i]\}$. There are several set of assumptions on δ and $f_{\tilde{\gamma}}$ that could be used. Condition (i) implies that the map $x \mapsto \mathbb{E}[h^{-1} K_h(\langle x - X_j, \tilde{\gamma} \rangle)]$ is bounded. This combined with the bounded conditional variance of U_i^0 and the finite second order moment of $\delta(X_j)$ yield $v_n^2 \leq c$ for some constant $c > 0$. Similar arguments could be combined with the condition (ii) to obtain the boundedness of v_n^2 . Finally, if condition (iii) is met, let $V_i = \langle X_i, \tilde{\gamma} \rangle$ and $\bar{\delta}(V_j) = \mathbb{E}[\delta(X_j) \mid V_j]$. Then using the inverse Fourier transform device we have

$$\begin{aligned} \mathbb{E}[\delta(X_j) h^{-1} K_h(V_i - V_j) \mid X_i] &= \mathbb{E} \left[\bar{\delta}(V_j) \int \exp\{it(V_i - V_j)\} \mathcal{F}[K](ht) dt \mid V_i \right] \\ &= \int_{\mathbb{R}} \exp\{itV_i\} \mathcal{F}[\bar{\delta} f_{\tilde{\gamma}}](t) \mathcal{F}[K](ht) dt. \end{aligned}$$

Take absolute value in the last integral, use the fact that $\mathcal{F}[\bar{\delta} f_{\tilde{\gamma}}] \in L^1(\mathbb{R})$, Lebesgue dominated convergence theorem and the fact that $\mathcal{F}[K](ht) \rightarrow \mathcal{F}[K](0)$ as $h \rightarrow 0$ to

deduce that $\mathbb{E}[\delta(X_j)h^{-1}K_h(V_i - V_j) \mid X_i]$ is bounded, and so is v_n^2 . Deduce that with any of the conditions (i) to (iii), $Q_{1n}(\tilde{\gamma}) = O_{\mathbb{P}}(n^{-1/2})$. Finally, it is easy to show that $\text{Var}[Q_{2n}(\tilde{\gamma})] \rightarrow 0$ (see, e.g., the proof of equation (26) in Lavergne and Patilea (2008)). It remain to study

$$\mathbb{E}[Q_{2n}(\tilde{\gamma})] = \int_{\mathbb{R}} |\mathcal{F}[\bar{\delta}f_{\tilde{\gamma}}]|^2(t) \mathcal{F}[K](ht) dt.$$

If condition (i) or (ii) holds true, $\bar{\delta}f_{\tilde{\gamma}} \in L^2(\mathbb{R})$ and by Plancherel theorem and Lebesgue dominated convergence theorem, $\mathbb{E}[Q_{2n}(\tilde{\gamma})] \rightarrow \int_{\mathbb{R}} |\bar{\delta}f_{\tilde{\gamma}}|^2 > 0$. If condition (iii) is met, $\mathcal{F}[\bar{\delta}f_{\tilde{\gamma}}] \in L^2(\mathbb{R})$ and since $\bar{\delta}f_{\tilde{\gamma}} \in L^1(\mathbb{R})$, deduce that $\bar{\delta}f_{\tilde{\gamma}} \in L^2(\mathbb{R})$ and continue with the same arguments. Deduce that with any of the conditions (i) to (iii), $Q_{2n}(\tilde{\gamma}) \asymp O_{\mathbb{P}}(1)$. Collecting the rates, we obtain the result. ■

6.4 Testing the functional linear model: proofs of the results

To simplify notation, in this section we write $\|\cdot\|$ instead of $\|\cdot\|_{L^2}$.

Proof of Lemma 4.1. By simple calculations, we have $\hat{U}_i = U_i - \langle \hat{b} - b, X_i - \bar{X}_n \rangle - \bar{U}_n$. Let $K_{h,ij}(\gamma)$ be a short notation for $K_h(\langle X_i - X_j, \gamma \rangle)$. We have the following decomposition

$$Q_n(\gamma; \hat{a}, \hat{b}) = Q_n(\gamma) - 2V_1(\gamma) - 2V_2(\gamma) + V_3(\gamma) + V_4(\gamma) + 2V_5(\gamma)$$

where

$$\begin{aligned} V_1 &= \frac{\bar{U}_n}{n(n-1)h} \sum_{1 \leq i \neq j \leq n} U_i K_{h,ij}(\gamma), \quad V_2 = \left\langle \hat{b} - b, \frac{1}{n(n-1)h} \sum_{i \neq j} U_i (X_j - \bar{X}_n) K_{h,ij}(\gamma) \right\rangle, \\ V_3 &= \frac{1}{n(n-1)h} \sum_{i \neq j} \langle \hat{b} - b, X_i - \bar{X}_n \rangle \langle \hat{b} - b, X_j - \bar{X}_n \rangle K_{h,ij}(\gamma) \\ V_4 &= \frac{\bar{U}_n^2}{n(n-1)h} \sum_{i \neq j} K_{h,ij}(\gamma), \quad V_5 = \bar{U}_n \left\langle \hat{b} - b, \frac{1}{n(n-1)h} \sum_{i \neq j} (X_j - \bar{X}_n) K_{h,ij}(\gamma) \right\rangle. \end{aligned}$$

To prove the rate in the first part of (4.14) we will show that

$$\sup_{\gamma \in S^p} nh^{1/2} |V_j| = o_{\mathbb{P}}(1),$$

for $j = 1$ to $j = 5$. First let us notice that by Fubini Theorem, $\mathbb{E}(\|\bar{X}_n - \mathbb{E}(X)\|^2) = n^{-1} \int_0^1 \text{Var}(X(t)) dt$ and so $\|\bar{X}_n - \mathbb{E}(X)\| = O_{\mathbb{P}}(n^{-1/2})$.

For V_1 use the fact that $\bar{U}_n = O_{\mathbb{P}}(n^{-1/2})$ and apply Lemma 6.3. Thus there exists $a > 0$ and $0 < \epsilon < 2a(1 - 2\zeta)$ such that

$$\sup_{\gamma \in S^p} nh^{1/2} |V_1| = nh^{1/2} O_{\mathbb{P}}(n^{-1/2}) O_{\mathbb{P}}(n^{-1/2+\epsilon} p^{1/2} h^{-1/2+a}) = o_{\mathbb{P}}(1).$$

To derive the rate of V_2 let us write

$$\begin{aligned}
V_2 &= \left\langle \widehat{b} - b, \frac{1}{n(n-1)h} \sum_{i \neq j} U_i \{X_j - \mathbb{E}(X)\} K_{h,ij}(\gamma) \right\rangle \\
&\quad - \left\langle \widehat{b} - b, \overline{X}_n - \mathbb{E}(X) \right\rangle \frac{1}{n(n-1)h} \sum_{i \neq j} U_i K_{h,ij}(\gamma) \\
&= V_{21} - V_{22}
\end{aligned}$$

By Cauchy-Schwarz inequality, the rate of $\|\overline{X}_n - \mathbb{E}(X)\|$ and Lemma 6.3, $\sup_{\gamma \in \mathcal{S}^p} |V_{22}| = o_{\mathbb{P}}(n^{-1/2} \|\widehat{b} - b\|) = o_{\mathbb{P}}(n^{-2\rho})$. For the rate of V_{21} let us write

$$\begin{aligned}
\frac{n-1}{n} V_{21} &= h^{-1} \left[\frac{1}{n} \sum_{1 \leq i \leq n} U_i K_{h,ij}(\gamma) \right] \frac{1}{n} \sum_{1 \leq j \leq n} \langle \widehat{b} - b, X_j - \mathbb{E}(X) \rangle \\
&\quad - \left\langle \widehat{b} - b, \frac{K(0)}{n^2 h} \sum_{1 \leq i \leq n} U_i \{X_i - \mathbb{E}(X)\} \right\rangle \\
&= V_{211} - V_{212}.
\end{aligned}$$

By Cauchy-Schwarz inequality and the law of large numbers with $|U_i| \|X_i - \mathbb{E}(X)\|$, $V_{212} = n^{-1} h^{-1} O_{\mathbb{P}}(1) O_{\mathbb{P}}(\|\widehat{b} - b\|)$. Next, by Cauchy-Schwarz inequality we can write

$$|V_{211}| \leq h^{-1} \left\{ \sup_{\gamma \in \mathcal{S}^p, t \in \mathbb{R}} |Z_n(\gamma, t)| \right\} \|\widehat{b} - b\| \|\overline{X}_n - \mathbb{E}(X)\|,$$

where

$$Z_n(\gamma, t) = \frac{1}{n} \sum_{1 \leq i \leq n} U_i K_h(\langle X_i, \gamma \rangle - t)$$

Apply Lemma 6.3 to deduce that there exists some small $\epsilon > 0$ such that

$$\sup_{\gamma \in \mathcal{S}^p} n h^{1/2} |V_{211}| = n h^{-1/2} O_{\mathbb{P}}(h^{1/2} n^{-1/2+\epsilon} p^{1/2}) O_{\mathbb{P}}(\|\widehat{b} - b\|) O_{\mathbb{P}}(n^{-1/2}) = o_{\mathbb{P}}(1).$$

Deduce that

$$\sup_{\gamma \in \mathcal{S}^p} n h^{1/2} |V_2| = o_{\mathbb{P}}(1).$$

For V_3 take absolute values and use Cauchy-Schwarz inequality and triangle inequality:

$$|V_3| \leq \frac{\|\widehat{b} - b\|^2}{n(n-1)h} \sum_{i \neq j} \{ \|X_i - \mathbb{E}(X_i)\| + \|\overline{X}_n - \mathbb{E}(X)\| \} \{ \|X_j - \mathbb{E}(X_j)\| + \|\overline{X}_n - \mathbb{E}(X)\| \} K_{h,ij}(\gamma).$$

Apply Lemma 6.2 three times and deduce that

$$\sup_{\gamma \in \mathcal{S}^p} n h^{1/2} |V_3| = n h^{1/2} O_{\mathbb{P}}(\|\widehat{b} - b\|^2) O_{\mathbb{P}}(1) = o_{\mathbb{P}}(1).$$

For V_4 apply Lemma 6.2 with $k_1 = 0$, $k_2 = 0$ and $l = 1$ and the rate of $\overline{U}_n$ to deduce

$$\sup_{\gamma \in \mathcal{S}^p} nh^{1/2}|V_4| = nh^{1/2}O_{\mathbb{P}}(n^{-1})O_{\mathbb{P}}(1) = o_{\mathbb{P}}(1).$$

Finally, let us write

$$\begin{aligned} V_5 &= \frac{\overline{U}_n}{n(n-1)h} \sum_{i \neq j} \langle \widehat{b} - b, X_j - \mathbb{E}(X) \rangle K_{h,ij}(\gamma) \\ &\quad - \langle \widehat{b} - b, \overline{X}_n - \mathbb{E}(X) \rangle \frac{\overline{U}_n}{n(n-1)h} \sum_{i \neq j} K_{h,ij}(\gamma) \\ &=: V_{51} + V_{52}. \end{aligned}$$

By Cauchy-Schwarz inequality and Lemma 6.2 with $k_1 = 0$, $k_2 = 2$, $l = 1$ and U_j^2 replaced by $\|X_j - \mathbb{E}(X_j)\|$,

$$\sup_{\gamma \in \mathcal{S}^p} nh^{1/2}|V_{51}| = nh^{1/2}O_{\mathbb{P}}(n^{-1/2})O_{\mathbb{P}}(\|\widehat{b} - b\|)O_{\mathbb{P}}(1) = n^{1/2}h^{1/2}O_{\mathbb{P}}(\|\widehat{b} - b\|) = o_{\mathbb{P}}(1).$$

Next, similar arguments for the uniform rate of V_{52} . Deduce that

$$\sup_{\gamma \in \mathcal{S}^p} nh^{1/2}|V_5| = o_{\mathbb{P}}(1).$$

The arguments for the rate in the second part of (4.14) are similar and hence will be omitted. ■

Proof of Lemma 4.3. Let $\widehat{g}$ (resp. $\widehat{g}^0$) be the random function defined in (4.16) that one would obtain under the null (resp. alternative) hypothesis, that is with covariates X_i and responses $a + \langle b, X_i \rangle + U_i^0$ (resp. $a + \langle b, X_i \rangle + \delta(X_i) + U_i^0$). We can write

$$\begin{aligned} \|\widehat{b}^0 - \widehat{b}\|^2 &= \sum_{j=1}^m (\widehat{b}_j^0 - \widehat{b}_j)^2 = \sum_{j=1}^m \widehat{\theta}_j^{-2} |\langle \widehat{g} - \widehat{g}^0, \widehat{\phi}_j \rangle|^2 \leq \sum_{j=1}^m \widehat{\theta}_j^{-2} \|\widehat{g} - \widehat{g}^0\|^2 \|\widehat{\phi}_j\|^2 \\ &= r_n^2 \int_0^1 \left(\frac{1}{n} \sum_{i=1}^n \delta(X_i) \{X_i(u) - \overline{X}_n(u)\} \right)^2 \sum_{j=1}^m \widehat{\theta}_j^{-2} =: r_n^2 \Gamma_n \sum_{j=1}^m \widehat{\theta}_j^{-2}. \end{aligned}$$

We have

$$\begin{aligned} \mathbb{E} \int_0^1 \left(\frac{1}{n} \sum_{i=1}^n \delta(X_i) \{X_i(u) - \mathbb{E}X_i(u)\} \right)^2 du &= \int_0^1 \mathbb{E} \left(\frac{1}{n} \sum_{i=1}^n \delta(X_i) \{X_i(u) - \mathbb{E}X_i(u)\} \right)^2 du \\ &= \frac{1}{n^2} \int_0^1 \sum_{i=1}^n \mathbb{E}[\delta^2(X_i) \{X_i(u) - \mathbb{E}X(u)\}^2] du \\ &= \frac{1}{n} \int_0^1 \mathbb{E}[\delta^2(X_1) \{X_1(u) - \mathbb{E}X_1(u)\}^2] du \\ &\leq \frac{1}{n} \mathbb{E}^{1/2}[\delta^4(X)] \mathbb{E}[\|X - \mathbb{E}X\|^2], \end{aligned}$$

where for the second equality we used the fact that $\mathbb{E}[\delta(X)\{X - \mathbb{E}X\}] = 0$. On the other hand, since $\mathbb{E}[\delta(X)] = 0$, by the law of large numbers $\overline{\delta(X)}_n = n^{-1} \sum_{i=1}^n \delta(X_i) = o_{\mathbb{P}}(1)$. Recall that $\|\overline{X}_n - \mathbb{E}(X)\| = O_{\mathbb{P}}(n^{-1/2})$. Deduce that

$$\int_0^1 \left(\frac{1}{n} \sum_{i=1}^n \delta(X_i) \{ \overline{X}_n(u) - \mathbb{E}X(u) \} \right)^2 du = \overline{\delta(X)}_n^2 \|\overline{X}_n - \mathbb{E}(X)\|^2 = o_{\mathbb{P}}(n^{-1}),$$

and finally that $\Gamma_n = O_{\mathbb{P}}(n^{-1})$. For the last part, use Theorem 1 of Hall and Horowitz (2007) which provides the rate of $\int_0^1 \{\widehat{b}^0(u) - b(u)\}^2 du$. Next, let us recall that Assumption P-(c) implies $\theta_j \geq cj^{-\alpha}$ for some constant c and thus $\sum_{j=1}^m \theta_j^{-2} = O(n^{(2\alpha+1)/(\alpha+2\beta)}) = o(n)$ provided that $m \asymp n^{1/(\alpha+2\beta)}$. Finally, one can deduce from the equations (5.6) to (5.9) of Hall and Horowitz (2007) that $\sum_{j=1}^m (\theta_j^{-2} - \widehat{\theta}_j^{-2}) = o_{\mathbb{P}}(n)$. Now the proof is complete. ■

Proof of Theorem 4.4. Like in the proof of Theorem 3.4, it suffice to show that $Q_n(\widetilde{\gamma}) \asymp_{\mathbb{P}} r_n^2$ for some fixed p sufficiently large and $\widetilde{\gamma} \in B_p$, where

$$Q_n(\widetilde{\gamma}) = \frac{1}{n(n-1)h} \sum_{i \neq j} \widehat{U}_i \widehat{U}_j K_h(\langle X_i - X_j, \widetilde{\gamma} \rangle).$$

Here $\widehat{U}_i$ are defined as in (4.19). There are 15 cross-product terms, all of them similar or identical to those analyzed in the proofs of Theorem 3.4 and Lemma 4.1. For the sake of brevity we omit the details. ■
